1. User Guide

Introduction

This user guide assumes that you are familiar with basic Windows techniques, such as using a mouse, manipulating window sizes and positions, scrolling etc.

From Power-Up

When the operating system has finished booting, and if prompted by the system, please log in. The default software installation places a shortcut to the OmniTek software on the desktop. The software will have been installed into 'c:\program files\omnitek\omnitek XR'. Consult the software installation guide as required.

By default the OmniTek XR application does not auto-start upon starting windows, so to start the application, double click either the 'OmniTek XR' icon on the desktop, or select 'OmniTek XR' from the Start menu/Programs/OmniTek.

If required, OmniTek XR can be set to start up automatically with Windows. This can be done by selecting 'Preferences' from the File menu, and then selecting 'Start with Windows'. Details on all of the menus in OmniTek XR starts on page 9.

Quick Start Guide

This section provides a basic guide to setting up the OmniTek application to use OmniTek XR. Since all OmniTek XR systems have the ability to send status messages over SNMP, by default the system attempts to connect to an SNMP service that may be running on the PC. If such a service cannot be found, you will see the following message.

If you do not need the SNMP functionality, this can be safely ignored. However it is possible to prevent this message appearing again. To do this, select 'SNMP Settings...' from the 'Configuration' menu. From the dialogue that appears, clear the tick box labeled 'Display error if connect unsuccessful'.

If you do need the SNMP service, then this needs to be separately installed. The SNMP service is a Microsoft operating system extension, and can be installed from the master Windows installation disk created by Microsoft. OmniTek have a document on the support section of our website explaining how this service may be installed. The OmniTek website address is www.omnitek.tv

Further details on the use of SNMP with OmniTek XR may be found in the SNMP appendix, starting on page 68.

Full Screen

After installation, XR defaults to running in Full Screen Mode. Press the ESCape button to toggle between normal mode and full screen mode. Full screen modes have little control ability, although different displays may be configured, and keyboard presets can be defined for common functionality. However they have the advantage of normal 'windows' modes of a less cluttered screen. Typically full screen modes have a black background which may make them more suitable in a colorist type of environment.

If you don't want to use full screen mode, you can change the default setting by selecting 'Configuration...' from the 'Full Screen' menu. Clear the tick box marked 'Startup in full-screen mode:', and click OK on the dialogue.

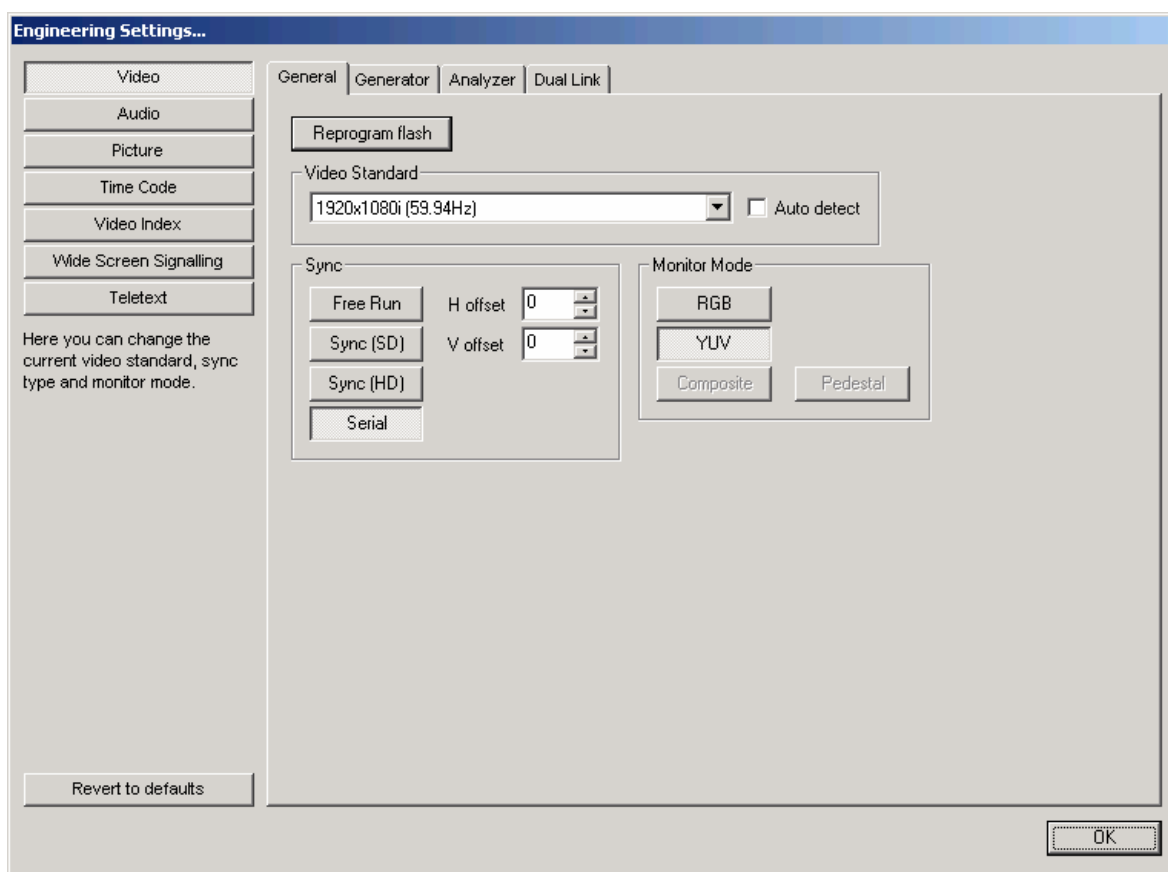

Details on Full Screen modes are on page 14.

Video Setup

Once the system is running normally within 'Windows, the next thing to do is to set the video standard you will be working in. Normally you will want to use 'Auto Detect', which may be set on the 'Video Standard' toolbar.

If the toolbar is not visible, it may be selected from the 'Show' menu. If you do not wish to use Auto Detect, you can select a specific standard from this toolbar. However you may also need to select the lock reference. This can be done by selecting 'Engineering...' from the configuration menu, and you then need to select the 'Video' section, and then the 'General' page.

It would be normal to select 'Serial' lock for a waveform monitor. Serial lock is selected automatically in 'Auto detect'.

For further details of video setup, please refer to page 13 of this manual.

Windows Layout

By default, the choice of windows and toolbars that was previously used will open. If these are not suitable, you can change which windows are open, and their positions, by using usual click and drag techniques. A full list of the available windows is on the 'Window' menu, although most windows have icon shortcuts.

If you have previously saved a system configuration, you can open a configuration, by selecting 'Open System Configuration' from the 'Configuration' menu. No system configuration files are included with the original installation.

Image Choice

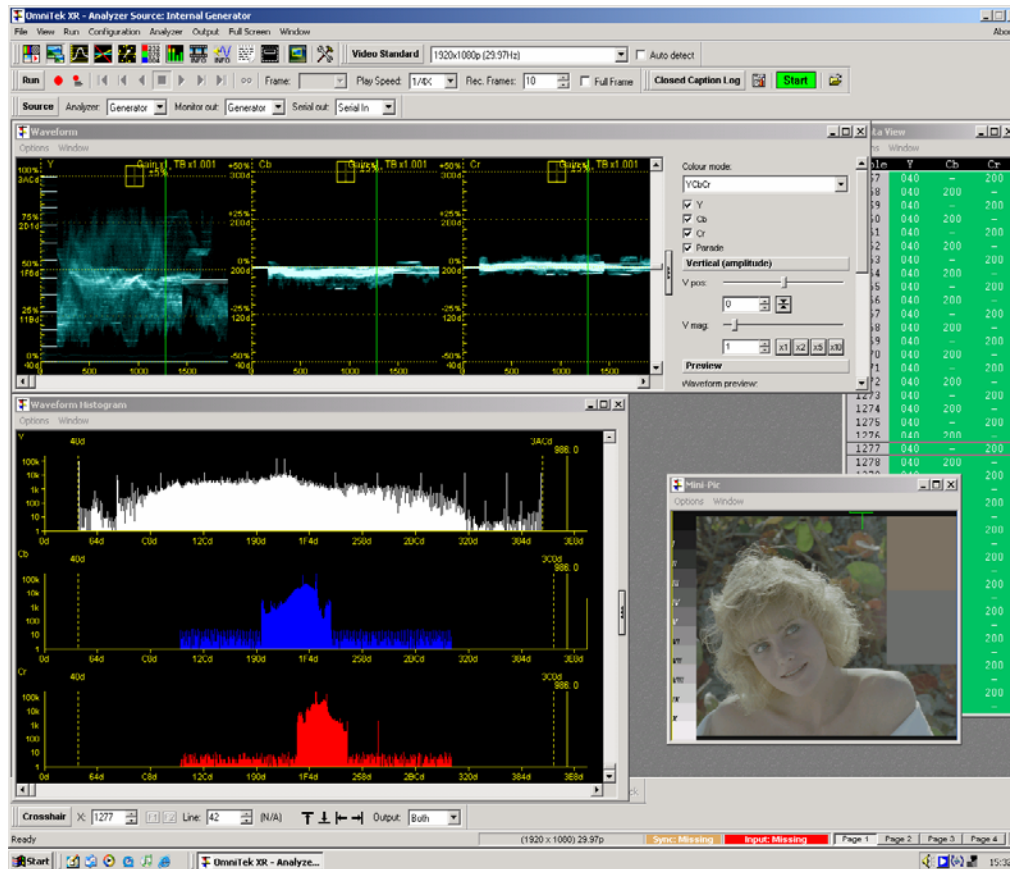

If you have an OmniTek XR system that also includes the Motion/Capture option, the full 'Source' toolbar will be present. If it is not visible, it can be turned on from the 'Show' menu on the main application. For normal use, you should set the analyser source to be the serial input, and you must select whichever of input A of Input B that you have connected to. If you also have the optional Motion and capture package, then you also have the option to set this to 'Generator', which is the setting to view data that has previously been captured. If you only have OmniTek XR without additional options, this toolbar only has the Input A/Input B switch, and the other items are automatically selected to monitor whichever link is selected.

Now that the chosen source is active, and the windows are present, you can use your OmniTek XR system. Complete details on OmniTek XR operations are contained in the next sections.

2. Detailed User Guide

Opening Window Description

With the OmniTek application running, you will see a window similar to that illustrated below, depending on what modules and options are present on your system.

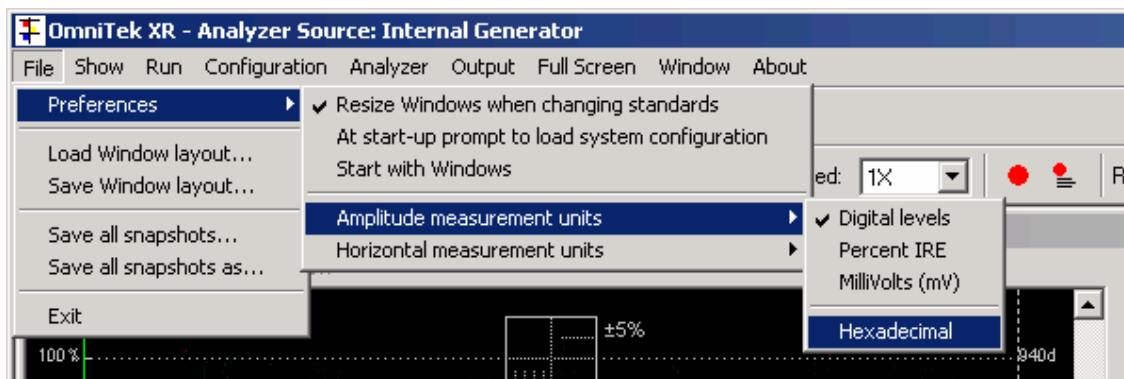

Dealing with each area in turn, and starting with the menus...

Menus

Each function on the menus is described in detail.

File Menu

The file menu has three main functions, Preferences, Window layouts, and snapshots.

Preferences

From the Preferences choice, you can enable automatic resizing of windows when changing standards. This can be useful if you are using the waveform windows at the default size for a given standard, as not all standards use the same aspect ratio.

When the OmniTek application is started, it automatically loads the configuration that was active when it was last closed. The second Preference choice here lets the system prompt you for choice of configuration instead. This can be useful if different people use the system, and have different requirements.

It should be noted that a System configuration contains 100% of your setup data. It includes which windows and toolbars are open, and their sizes and positions, what video format, what locking reference, what options have been set for the optional error logging package etc.

The 'Start with Windows' menu entry forces OmniTek XR to start up at the same time as you log into Windows. This saves you having to start the application from the desktop, or Start menu.

There are two menu choices for measurement units. These affect all uses of the related measurement units. For example, by selecting the amplitude measurement units to be milli-volts, then amplitude measurements made using the cursors will be in milli-volts, the minimum and maximum thresholds will be expressed in milli-volts, and all the waveform graticules will be shown in milli-volts. If the values are expressed as digital levels, this is as a 10 bit number from 0 to 1023, which can also be shown in hexadecimal.

Similarly the horizontal measurement units can be shown as time, in uS, or as pixel sample number. Hence the horizontal axis on the waveform graticules will show a different range of sample number depending on the current video format.

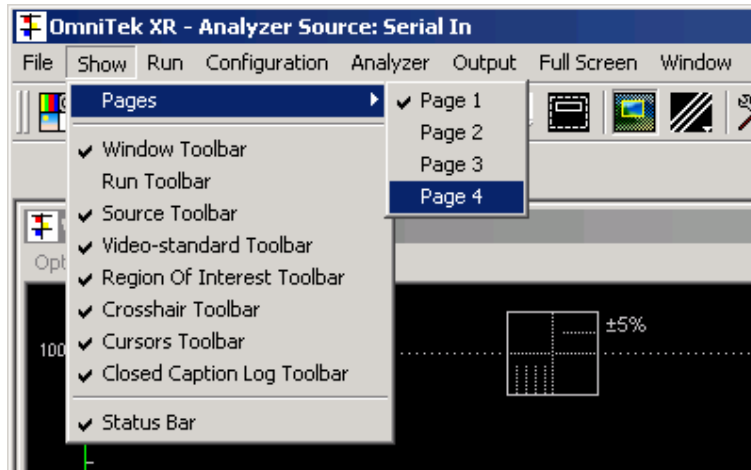

Related to these global settings for measurement units, please note that two separate waveform calibrations are available. These are the SMPTE range of 64 to 940/960, and the full range of 0 to 1023. The setting for this can be changed using the Option menu in the waveform window, selecting the Graticule submenu, and then choosing either 'SMPTE range' or 'Full range'. Full details on the menus in the waveform window are on page 37.

Windows Layouts, and Snapshots

It is possible to load and save windows layouts. These layouts only save the size and position, and status of the windows, so engineering settings like video format are unchanged.

Window snapshots let you save the current contents of a window to a file in an appropriate format. If all snapshots are saved, then the contents of every **open** window is saved. Waveform, histogram and vectorscope windows are saved as bitmap images, and the dataview window is saved as a text file. It is also possible to save individual windows, using a menu selection on each window, which is detailed in the Window menus section, starting on page 37.

Show Menu

The main desktop application has four work surfaces available. You can just use one. However, if preferred, you can split the various windows amongst the four work surfaces, which may help to keep an uncluttered screen. The Show menu gives access to the four different pages, although you can also use the four buttons available on the bottom right hand side of the status bar (see page 65 for details on status bar). For each of these four work surfaces, you can define which toolbars are present, and which windows are open. This is easily done by selecting a given work surface, and once in that surface, open/close the windows and toolbars as required. This will not affect what toolbars and windows are open in other windows. Note that the four buttons on the status bar are only correctly available if your screen resolution is set to a minimum of 1280 * 1024. For smaller resolutions, some of the buttons will be off the edge of the display. We always recommend using 1280 * 1024 or larger displays.

The Show menu also lets you individually enable or disable each toolbar. The available toolbars are

Window	main controls for the OmniTek application. It lets you open/close the main operating windows, plus controls a few special purpose features.
Run	transport controls to control sequence playout (only if the Motion/Capture option is present)
Source	displays the main router controls, which select the source for the analyser, the source for the monitoring output, and the source for the serial output (only if Motion/Capture option is present), and for all versions, control the A/B input switch
Video-Standard	a small toolbar that lets you change video standard without going into the main Engineering dialogue
Region Of Interest	This is a separate window that acts in conjunction with the waveform and vectorscope windows, and provides fine detailed control over which portion of the image is used to create waveforms etc. This is described in detail on page 43.
Crosshairs	position control and readback of main cursor
Cursors	measurement cursors for time and amplitude
Closed Caption Log	This provides access to logging closed caption data to an XML file.
Status bar	at bottom of main window – provides video standard details.

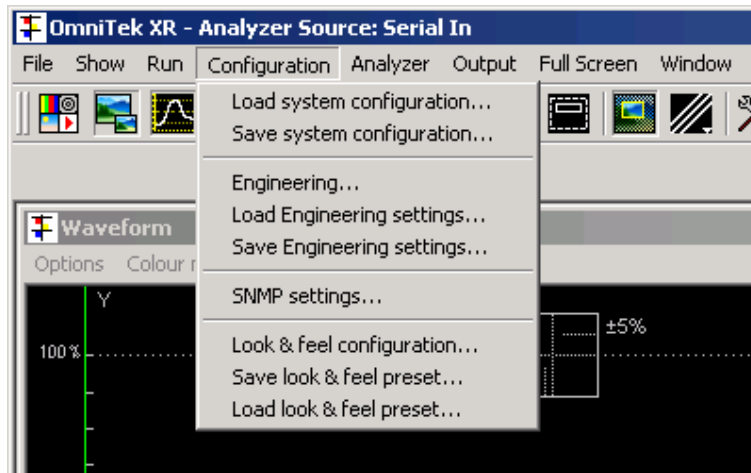

As a standard 'Windows' feature, all toolbars can be moved around on the main toolbar region, or can be undocked from this region. Toolbars can be docked at either the top of bottom of the main application window. It is not possible to dock on the left or right edge.

Run Menu

The Run menu is provided to duplicate the transport controls included on the Run toolbar. It is anticipated that the controls will normally be used from the toolbar, as this is usually much quicker to use. However the menu is provided such that automated keyboard macros may be used, as menu items can always be selected by combinations of key presses.

Items available on the Run menu are 'Play', 'Stop', 'Jog' etc, and are all described in the section on the Run toolbar, on page 27, along with the 'Time Shift' feature that is included only as part of the 'Advanced Option Package'.

Configuration Menu

This menu contains four sections.

System Configuration

This section lets you load and save entire system configuration settings. These control 100% of the machines settings, such that you can copy the system configuration settings from one machine to another, and have it set up identically, with the same windows open, in the same positions etc. The current settings are always saved when the application is closed, and by default will be loaded again when the application restarts. The system configuration is saved in a .ods file.

Engineering Configuration

The Engineering settings comprise the settings made in the Engineering dialogue box, for which full details can be found on page 17.

When Engineering settings are saved and loaded, the layout of the windows and toolbars is unaffected. Engineering settings are stored in a .ode file.

SNMP Configuration

The SNMP settings control the SNMP configuration, which are only required as part of the logging package. Consequently details of SNMP configuration, as well as full details on the logging functionality, are included in the appendix starting on page 70.

Look and Feel Configuration

Look and Feel presets are used to let you copy the user setup from one system to another. The configuration lets you specify that certain display items sue a specific colour, and these settings can then be saved and loaded as presets.

Analyzer Menu

The Analyzer menu is shown above. A variety of functions for the main OmniTek XR analyzer module are available here. Functions used most commonly are available from icons on the main toolbar, whilst features that are rarely used can only be controlled from this menu. Each menu item is described in turn.

Input to Analyzer

Controls whether the main View module looks at the serial input, or at the Generator (only if motion/capture option is present). This control can also be changed from the 'Source' toolbar.

Interpolator

This enables the interpolator that controls how the hardware samples and displays the incoming data. Occasionally a clearer result can be obtained by turning the interpolator off, but usually it would be left on.

Low Pass

This turns on a low pass filter. The frequency response changes depending on whether the current video format is SD or HD.

TRS Pass

By default, TRS data is not displayed in the mini-pic, waveform view, or vectorscope. This control lets you enable the display of TRS. The data shown in the dataview will always contain any TRS data present on the signal, regardless of the state of this control.

Closed Caption Source

Closed caption data from the serial input can be decoded and displayed on the mini-pic, or written into an XML log file. The data source can be from line 21, EIA608, or EIA708. Note that in order to display on the mini-pic, this display must be enabled, which is done from the 'Options' menu of the mini-pic window. Details on this on page 44.

Output Menu

This menu controls features relating to the output video.

OmniTek XR can display a crosshair on the output. The crosshair is always centred over the sample currently displayed in the dataview. The crosshair can appear on the analogue (monitoring) output, or the serial digital output, or on both outputs.

XR can detect when the incoming video is out of range, based on the range thresholds set up in the Engineering menu (see page 20 for details), and key out any erroneous pixels and replace them with a flashing black and white pattern. This error display can be included on the analogue output, the digital output, or both outputs. The menu selection determines which output is used to display the flashing pattern. Note that range errors can also be highlighted onto the YUV waveforms. The same thresholds are used to determine out of range, but the choice of highlighting is set on the Options/Data menu, from within the waveform window.

Similarly, XR can detect when the incoming video (YUV data) is outside of valid RGB colour space. Again out of gamut pixels can be highlighted on either output with the flashing pattern. In the same way, out of gamut pixels can also be shown on the RGB waveforms. Note it is not possible to highlight pixels with range errors and pixels with gamut errors simultaneously on the waveforms, as pixels with range errors can only be seen when displaying YUV waveforms, and pixels with gamut errors can only be seen when displaying RGB waveforms.

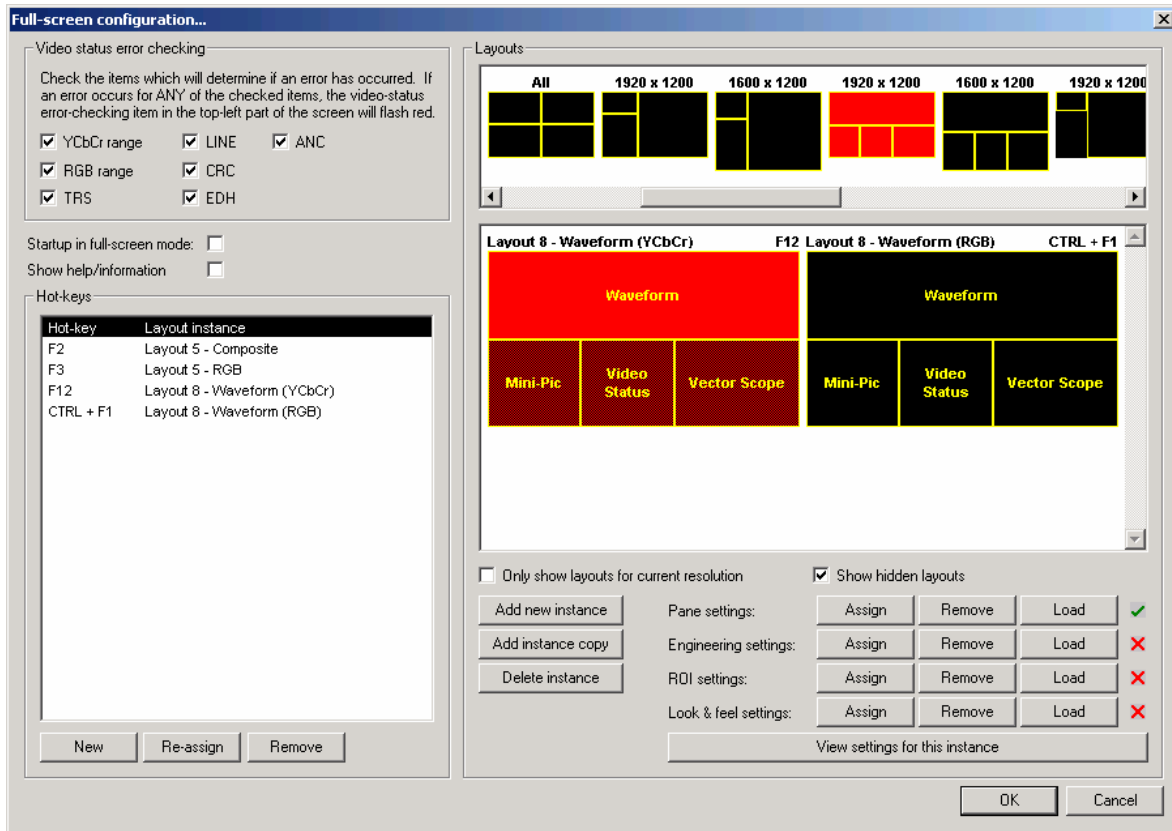

Full Screen Menu

As well as operating within a convention 'window', OmniTek XR has many display modes that can operate within a 'full-screen' environment. This menu is concerned with these modes.

From the initial menu you can directly launch a specific view into full screen mode. When in full screen, press 'ESCAPE' to return to the normal view. Pressing ESCAPE again will go directly to full screen, to the view last looked at.

By selecting 'Configuration', you can adjust various settings.

The full screen display includes a global error detection display. This shows as ERRORS, and the display is the logical AND of all of the conditions that are checked in the 'Video status error checking' section. This information, as well as a small amount of help information, can be displayed at the top and bottom of the full screen displays, by clicking the 'Show Help/Information' box. When in the full screen mode, pressing the 'I' button also toggles display of the help information.

It is possible to start up the application and directly start in full screen, by selecting in the 'Startup in full-screen mode:' box.

Instructions for the use of the Layout Builder.

OmniTek XR contains a full screen layout editor which provides a host of powerful features in an easy to use format. A new screen layout is normally created by taking a copy of an existing template layout, then assigning elements such as waveforms, or vectors, to each pane in the layout. The settings for each element can be customized, and a hotkey assigned to the final layout. It is even possible to have individual engineering settings for each layout.

The loaded screen layouts that match your current screen resolution will always be shown in the 'Layouts' section at the top of the dialogue. Start by scrolling through this, and selecting the required template. If there is not a template suitable for your requirement, these can be created by editing a text .ini file. Please contact OmniTek to see if an alternative template can be supplied, or for help on how to edit the .ini file.

Once you have selected a template layout, the window below will show all currently existing instances of that template layout. It is possible that not all templates will have been used, so for some, the window will be empty.

If there are existing instances, they can be edited. To create a new instance, select the 'Add new instance' button. A new instance appears, with the window panes unassigned, and the whole thing highlighted in dark red, and an individual pane highlighted in a lighter red.

Similarly you can copy an existing instance including all of its settings, in order to produce a similar layout, and you can delete instances no longer required.

To edit a new or existing instance, start by double clicking one pane within the instance, or alternatively right click over the pane, and select 'Change pane type'. From the popup window, select your choice of waveform, vectorscope etc. Repeat this process for the other panes within the instance.

Initially the new instance will have a default name shown directly above it, of the form 'layout 3'. Double click on this name, and a popup appears that lets you rename the instance.

Assigning Settings

By default, no specific settings are assigned to the various portions of the full screen view. So when you enter a full screen view, each pane will adopt the current settings of the related window within the normal environment. For example, the waveforms in a given full screen view could show YUV. Go back to the windows environment, and change the waveform display to RGB, and then go back into the full screen display. If no settings have been assigned, then the waveforms will now be showed in RGB format.

However, if, for the given full screen view, the waveforms had been assigned to YUV, they would always be YUV, regardless of the setting within the Windows environment.

To assign settings to a pane, select the pane, and click 'Assign' from the 'Pane settings' section. Applicable settings include the choice of YUV or RGB, and whether the waveforms are shown at normal size, or are stretched to a larger size.

If at a later stage you wish to change the settings previously assigned, then 'Load' the pane settings back into the Windows version, change them to suit your requirement, and re 'Assign' them back.

Similarly it is possible to entirely 'Remove' the pane settings if required.

As well as assign Pane settings, it is possible to separately assign the Engineering settings, the ROI settings, and the Look and Feel settings.

The Engineering settings includes things like video standard.

ROI settings includes things like all line versus single line view, which can also be configured to look at specific lines. This is very useful, as three identical views could be configured, except that the first view is All line, the second view is only the first active line, and the third view could be only the last active line. With these views assigned to separate hotkeys on the keyboard, it is very fast to switch between these different settings.

The Look & Feel settings include things like the colour of the waveforms.

Be warned that the various assignments can still be in force after switching from a full screen view with an assignment. For example, if F4 switches to a given arrangement of panes, but also switches to NTSC, then the whole unit will remain in NTSC until you change it back, or select another hotkey that has an Engineering setting assigned to it. So really the Engineering settings should either never be assign, or should be assigned to every possible hotkey.

Whilst certain controls can be assigned to different full screen displays, greater versatility and greater ease of use can exist by using Presets (see page 66) to control simple functions like switching between single line and multi line view.

Having chosen your full screen format, chosen displays for each pane, and configured each pane to suit your requirements, the last thing to do is to assign a hot key to that layout. Right click over the layout image, and select 'Assign hot key' from the menu that will appear. When the hot key dialogue appears, press the key or key combination that

you wish to use, and press OK (and do not press Enter on the keyboard, as otherwise that will be picked as the hotkey assignment). Note that certain choices are not available, as these are already assigned to the OmniTek application, or to the operating system environment. Once a valid hot key has been assigned, it will be indicated above the right hand corner of the layout image. Subsequent presses of the relevant hot key will switch LAB directly into full screen mode into the chosen layout. The list of all assigned hot keys appears on the left of this dialogue. Hot key assignments can also be deleted or changed here.

Window Menu

This menu lets you select a given window, and bring it to the front of the other windows.

About Menu

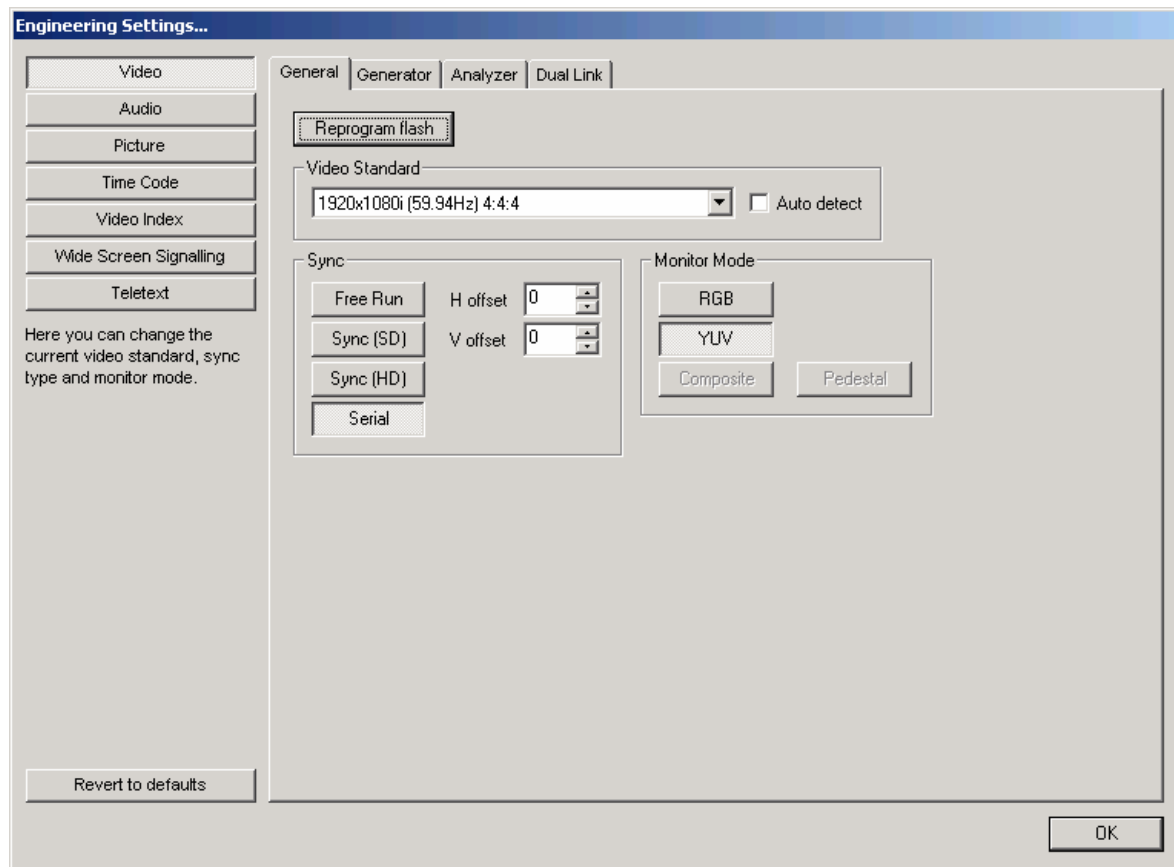

The About menu shows you what software versions you are running, and shows your license key information. You may need some of this information if you are making a support call to your dealer.

The About menu can always be found at the very right hand edge of the menu bar.

Engineering Controls (part of Configuration menu)

When using OmniTek XR, perhaps the most important controls are the Engineering controls. From here you determine the entire configuration of the system, in terms of what video format to use, video lock reference, etc. Each section of the Engineering menu selection will now be described in detail.

Engineering - Video - General

Reprogram Flash

At the top of the dialogue box, there is a button called 'Reprogram Flash'. The main video processing on OmniTek products is done using a large FPGA. The firmware for this FPGA may be changed by downloading a new design to the onboard Flash memory. In this way it is possible to improve the video processing remotely. When a new software update is installed, the software should automatically detect the presence of new firmware, and reprogram the flash. This button lets you do the process manually. Note that it is necessary to close all OmniTek applications before reprogramming the flash, so any grabbed images and sequences should be saved first.

Once you have pressed this button, you are prompted for the location of the binary file that will be used to program the flash. Each software release includes several different binary files, and these will always be stored in `c:\program files\omnitek\omnitek xr`. The correct file to use is 'alphaflash_cypress.bin'. Once the file is loaded, the flash will be reprogrammed. This operation takes a little over thirty seconds to complete.

Set Video Standard

The current video standard is shown in the box. Clicking the drop down arrow, and selecting from one of the available choices can change it.

Sync Type/Position

If OmniTek XR is to be locked to reference syncs, select either (Analog) Sync (SD), (Analog) Sync (HD) or Serial. SD sync signals are assumed to be bi-level, and HD sync signals are assumed to be tri-level. If OmniTek XR is not going to be locked to external syncs, then select Free. It is perfectly valid to lock to SD syncs whilst working in HD, as long as the format has the same update rates. This is particularly useful if an HD SPG is not available, but you need to use analog reference locking.

If the OmniTek system is used to look at an internally generated pattern using the Motion/Capture option, then it is possible to alter the relative position of the output video with respect to the lock reference by adjusting the horizontal and vertical offset controls.

However, if the OmniTek system is being used to look at a live video source, then the H and V offset controls should both be left at zero, as no real timing control is possible for a live video source. If OmniTek XR is to be used to analyse incoming video, then we recommend that the XR is locked to that incoming serial video.

Monitoring Output

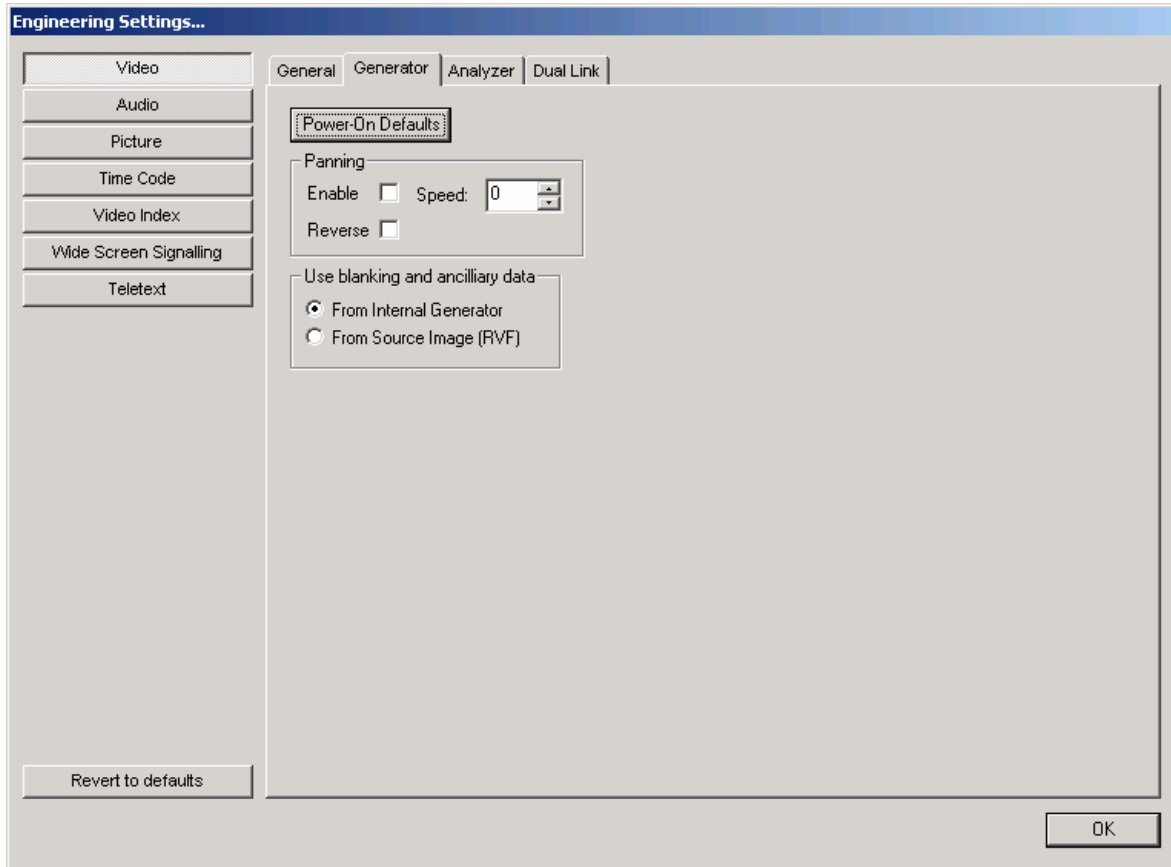

OmniTek XR provides an analog non-broadcast grade monitoring output, on a 9-way mini din socket. The unit will be supplied with a breakout cable, which will either connect this socket to an SVGA connector, or to 5 BNCs, depending on configuration at the time of purchase. The video on this connector may be set to RGB or YPbPr, depending on the Monitor Mode setting. Please note that if the monitor output is connected to an SVGA monitor, then it will be necessary to use the RGB setting. Also note that in some standards, there will be HD video on this connector, which will probably exceed the bandwidth of cheap SVGA monitors. When the standard is set to NTSC or PAL, it is possible to select Composite and Pedestal options for the monitor output. With the standard BNC cable, the composite signal will be on the green BNC connector. In this mode, there is also an S-Video output. The luma channel is on the red BNC, and the chroma channel is on the blue BNC.

The green BNC will have tri-level sync on it.

Note that the analog output will run at the frame rate chosen for the video standard. It is possible that some analog monitors will not be able to lock to some of the frame rates that are available, in particular the very low rates used by the HDSL formats.

Engineering - Video – Generator

This page of the dialogue box is only available if the OmniTek XR system includes the Motion/Capture option.

The controls relate only to video generated in the Motion/Capture module.

Power on Defaults

'Power on Defaults' is used to force the analogue and serial outputs from the OmniTek XR to a chosen video format, within half of one second from power up of the system, and therefore before the operating system has had time to load. The settings will remain in force until the OmniTek XR application has initialized, when the program settings will overwrite the power up settings. To use this feature, just click the button, and the current settings will be written into the reprogrammable hardware on the OmniTek card.

Panning

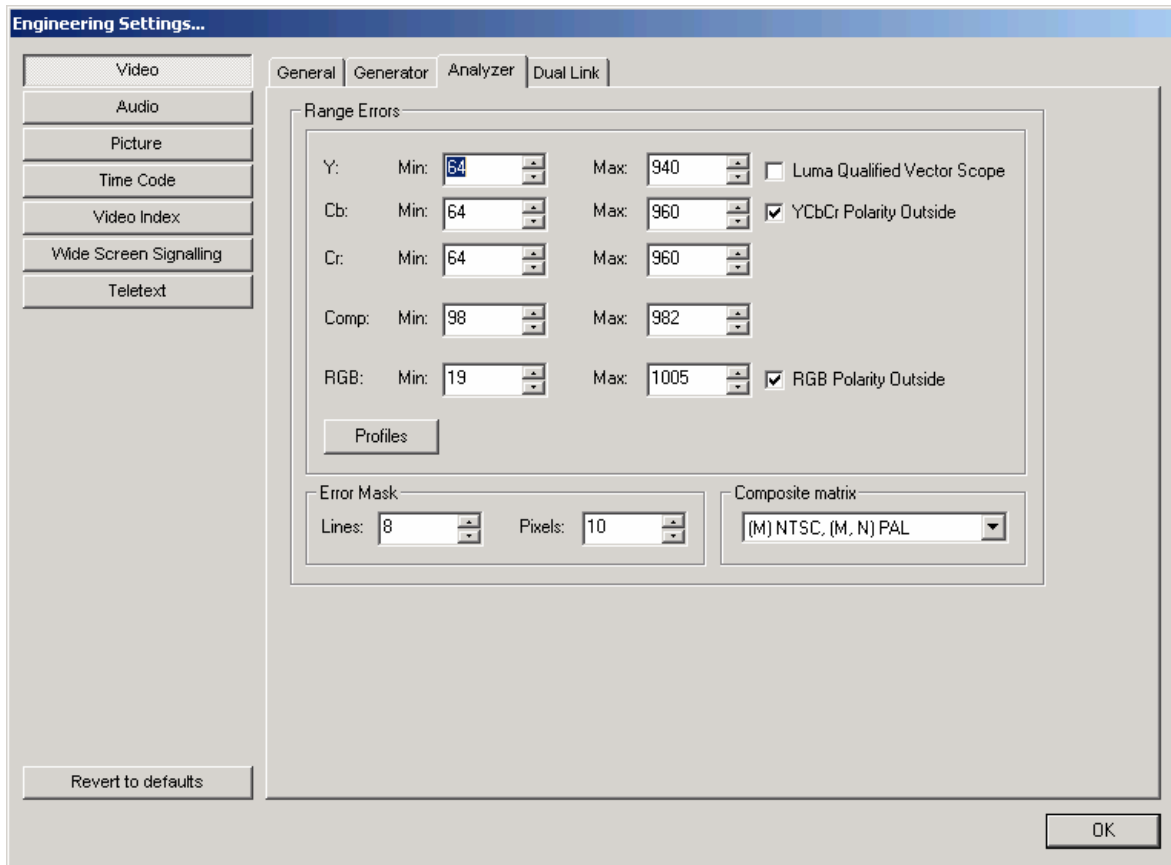

By selecting enable, and a speed from 1 to 31, it is possible to have the image/sequence continually scroll sideways. Reverse lets you change direction. If you keep 'enable' selected, and drop the speed to 0, the image will stop scrolling, and remain at its current position. To return the image to the normal position, clear the 'enable' box.

Please note that one side of the image will drop one line during panning, since the image in effect, wraps around from the right hand edge onto the start of the next line, on the left hand edge.

Blanking and Ancillary Data Payout

Under 'Use blanking and ancillary data', select 'from internal generator', to have the audio, video index, wide screen signalling facilities in XR available to insert data onto the output, and remove the entire ancillary data packets from the original source material. This is described in more detail on page 58. Note that this is only available if the Advanced option is present. If this option is not included, then the blanking and ancillary data can only be generated from the internal generator.

Engineering - Video - Analyzer

OmniTek XR always works with actual video data, which as a 10 bit value will be a number from 0 to 1023. Sometimes it is easier to understand the operation of OmniTek XR if these ranges are scaled to more familiar units. By choosing 'Preferences' from the File menu of the main application, you will see some options to change the 'Amplitude measurement units' from digital levels to Percent IRE, or to Millivolts. You can also specify the decimal or hexadecimal base when looking at digital levels. The setting on the File menu will affect all of the video values shown on this dialogue.

OmniTek XR detects and count luma/chroma range errors. The exact levels that trigger an error are determined in this dialogue. For range checking, you can specify the minimum and maximum IN RANGE values for luma and each chroma component. Values less than the minimum, or greater than the maximum will be treated as an error. It is possible to detect values within the specified ranges, or outside the ranges, by clicking the 'YPbPr Polarity outside' box. Many companies set the minimum value for luma and chroma to 0%, which equates to 64 as a digital video level. The maximum values would normally be set to 100%, which equates to 940 digital video levels for luma, and 960 for the two chroma components.

Similarly, XR detects and counts gamut errors, which are calculated by converting the data into RGB colourspace, and then noting if any pixels are outside the RGB colour cube. Many companies set the minimum gamut value to be -5%, and the maximum to be +105%.

An error mask is also provided. This is used to remove the top and bottom lines, and the pixels near the edges, from the error checking process. This is intended to handle video where the edges near the sync are corrupted. The mask has no other effect on the data, which will still be grabbed, displayed on the waveform views etc, in their entirety.

The mask settings are symmetrical, ie however many lines are specified here, then this number of active lines will be masked out, on both fields, at both the top and bottom of the image. Similarly, the number of pixels entered will effect both picture edges, starting from the end active pixel in each case.

The settings for luma, chroma or gamut ranges and the error mask may be saved in a profile. Click the save range settings button, and the settings will be saved to a named profile. When OmniTek XR is started, the last used profile is automatically loaded. However, a new profile may be loaded at any time.

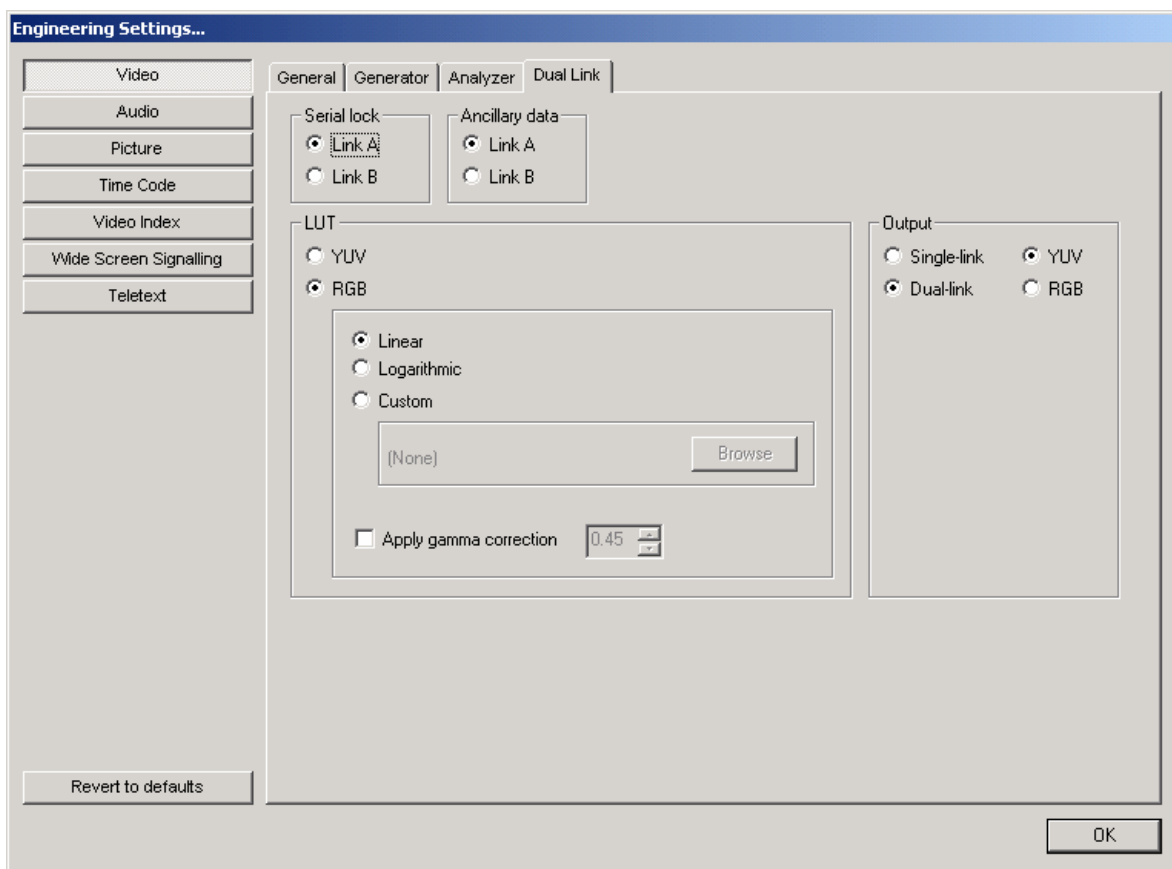

As well as detecting errors, this dialogue provides access to a special mode of operation for the vectorscope, the "luma qualified vectorscope". By using this control, the only pixels that are used to create the vectorscope are those whose luma lies within the range specified for the luma error range checking. This implies it is not possible to use both features at the same time.

However, you can use the luma qualified vectorscope to, for example, only display the vectors for pixels that are nearly black, which can be very useful for colourists.

It is possible to define a 'Preset' to enter and exit luma qualified vectorscope mode, which makes this very easy to use. See page 66 for details on defining presets.

Engineering - Video – Dual Link (Option)

If your XR system includes the Dual Link option, there will be an additional page on the Video section, to control Dual Link specific settings.

Since there are two coax cables for dual link, you can set the system to lock off either input, and you can similarly choose to decode ancillary data from either input.

If your dual link signal is in YUV format, the data values are not processed. However, if you are using RGB data, the values can be processed in a lookup table. The linear setting leaves data unchanged. The Logarithmic setting applies a standard log lookup table to the data. Finally, selecting Custom uses your own lookup table. This needs to be loaded in using the 'Browse' button, but once it has been loaded, you can switch between it and the other settings without having to reload. Custom lookup tables should be in CSV (comma separated variable) format. LUTs are included with OmniTek XR for Sony SR, and Thomson Viper cameras, and of course these can be modified to create complete custom LUTs. The supplied LUTs are located in program files\omnitek\omnitek xr.

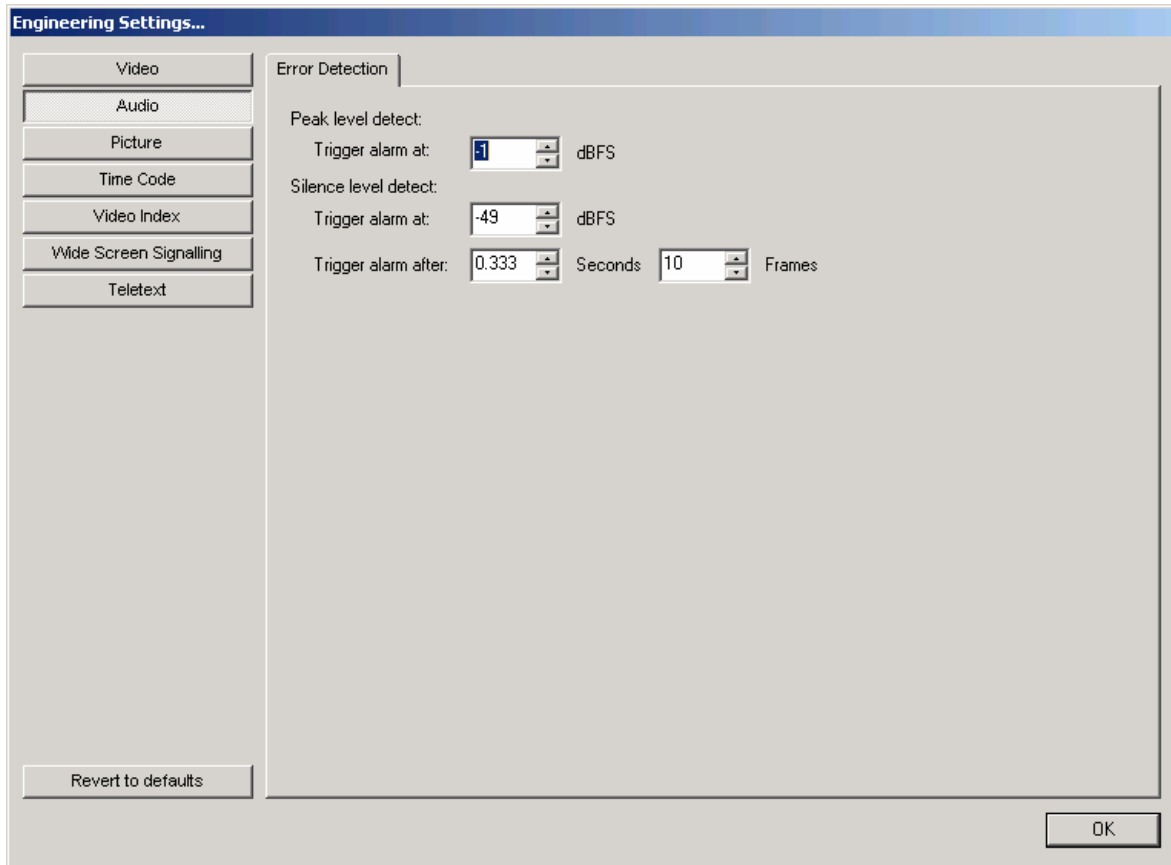

Finally, a variable level of gamma correction may be applied to the video.

Note that whilst the lookup table adjusts how the waveforms and vectorscope are displayed, the data shown in the Dataview window is always the exact data contained upon the serial inputs.

If your Dual Link system also includes the optional Motion/capture module, then you can also produce a dual link output from the system. The output can be configured as either single link or dual link. If dual link, then the output can be selected as either YUV or RGB. If you do not have the motion/capture option, then only a single link, YUV format, output is available, regardless of whether the input is dual link or single link.

Engineering – Audio – Error Detection

OmniTek XR has audio peak and silence detection features, which are configured here.

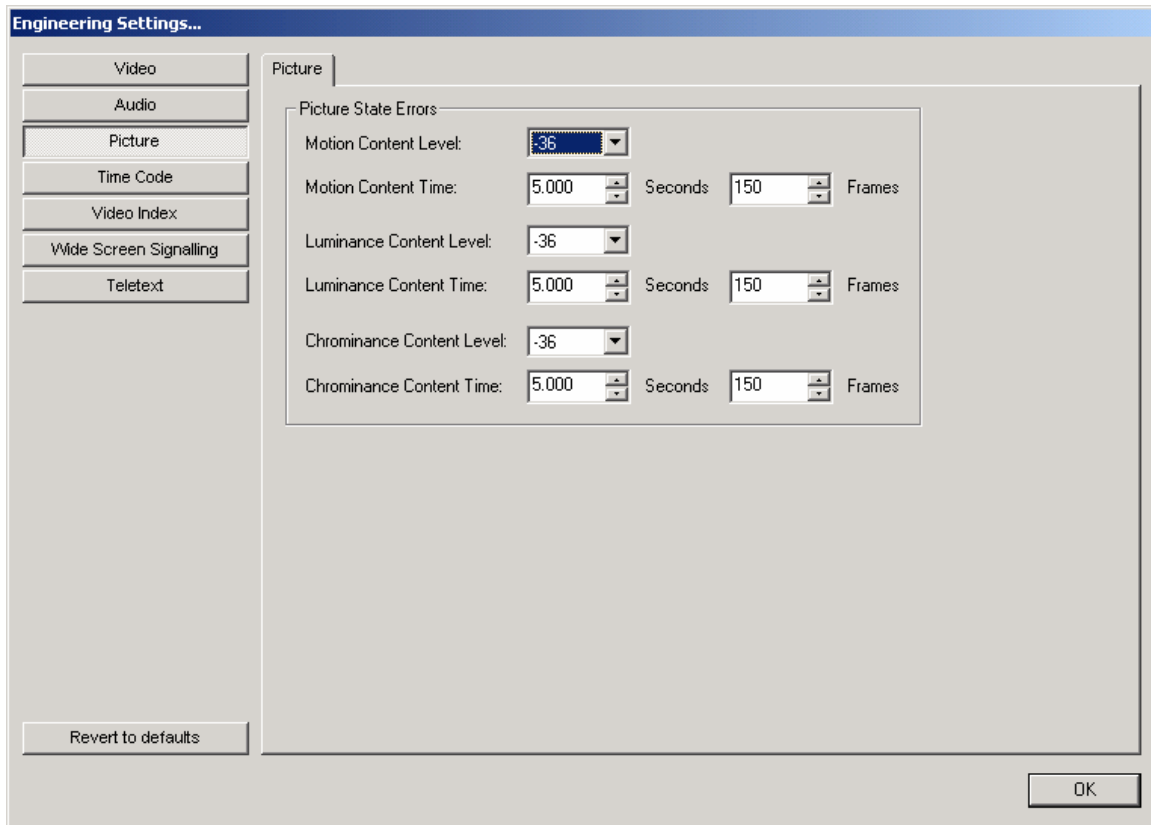

The levels for the peak and silence detector may each be adjusted. Both alarms are only triggered after a set period of time has elapsed. This time interval may be entered in seconds or in frames. These settings are stored as part of an overall system configuration file, and are also saved when the application is closed.

The levels, and the timeout are relevant to the display of audio errors in the audio status box, as well as being used as part of the logging module, and for the SNMP module, both of which are standard with all XR systems.

Note that in conjunction with the Motion/Capture module, XR can generate video test images and sequences. However XR has no specific audio generation facilities.

Engineering – Picture

OmniTek XR can detect whether the picture is moving or frozen, or whether the picture has gone to black, or to black and white. The settings for the detectors may be configured here.

- **Motion Content**
A level of filtering can be applied to the picture. This is designed to accommodate an analog VTR that is parked on a single frame. The picture will be frozen, but the varying analog noise from the VTR will mean that each frame is actually slightly different. The filter setting removes a certain amount of noise, and the filtered image is then tested. The filtering is actually based on an equivalent noise level. Thus if you have a uniform image, and add -36dB of noise to it, then setting this value to -36dB means that the detector is on the threshold of noting the image as moving, or not. Following on from this, a setting of -6dB will filter out high levels of noise, and a setting of -54dB will only filter out a very tiny amount of noise.
- **Luma Content**
This control works in exactly the same way as the Motion Content control, and detects if the picture is black.
- **Chroma Content**
This control works in exactly the same way as the Motion Content control, and detects if the picture is black and white.

The results of these detectors are displayed in the Video Status window, described from page 48 of this manual. These same detectors may also be used in the logging, or SNMP alerts, described on page 68.

Engineering - Timecode Reader Configuration

All OmniTek XR systems include a VITC and ATC reader.

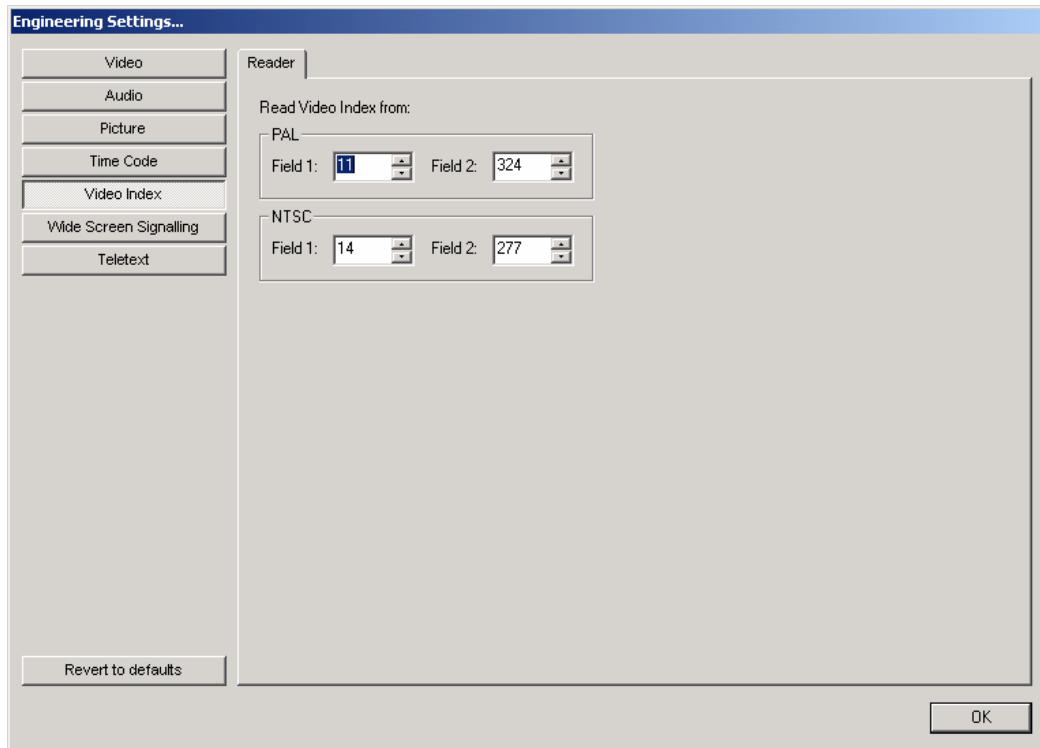

ATC is available in SD and HD, but VITC is only read in SD, and it is necessary to configure which lines are to be used to read the timecode data. The typical lines used for PAL and NTSC are shown above.

For ATC, noting that ATC is simply a packet that can contain different types of timecode, it is necessary to specify whether you intend to read LTC, VITC1 or VITC2. Note that the term LTC here refers to LTC data embedded within an ATC packet, not to the older form of LTC transmitted in an analog format.

Engineering - Video Index Reader Configuration

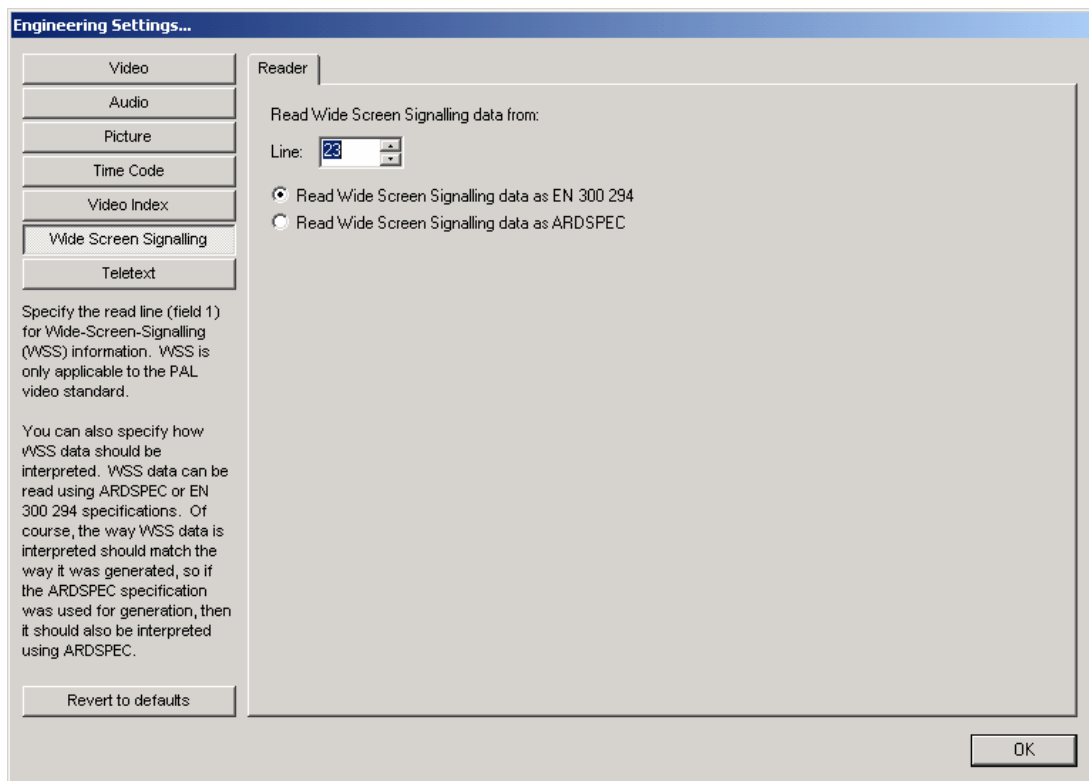

OmniTek XR includes a Video Index reader.

Video Index can only be read in SD.

Engineering - Wide Screen Signalling (Line 23) Reader Configuration

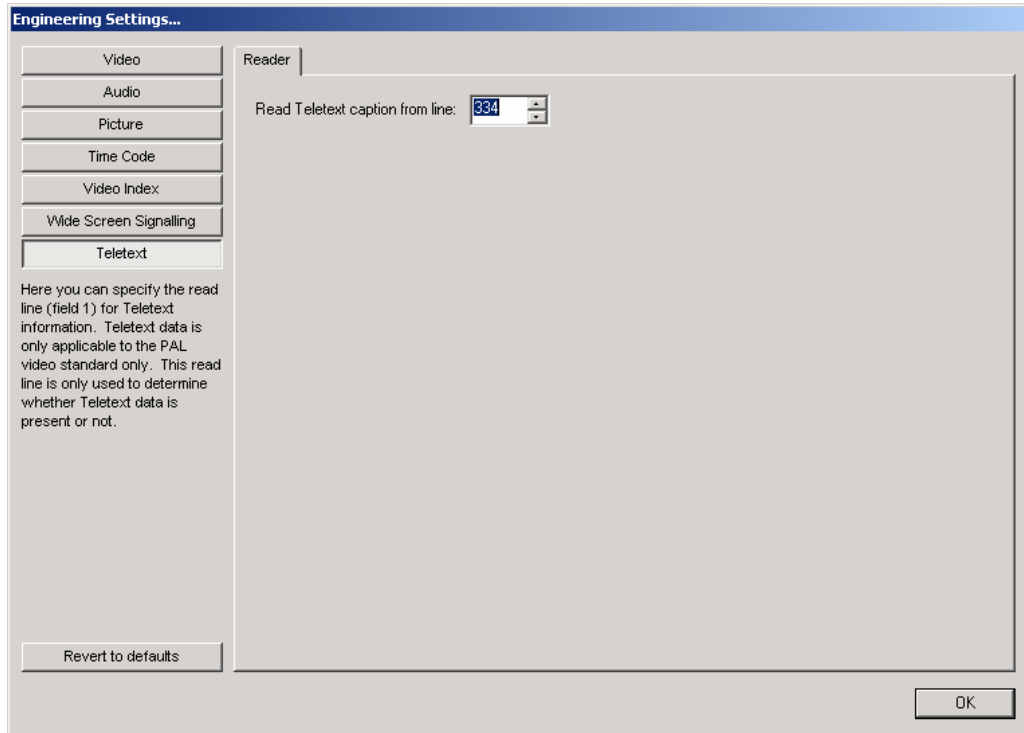

The standard OmniTek XR system can detect and decode wide screen signalling data that is contained in line 23 of a PAL/625 signal.

XR can interpret the data either as per EN300294, or as modified by ARDSPEC.

Engineering - Teletext Detector Configuration

OmniTek XR can detect the presence of teletext data in the incoming video.

It is necessary to specify the correct line number that contains the data.

This feature only works in SD.

3 Toolbar Icons

Beneath the menu there is a row of icons, referred to collectively as the toolbars, which provide direct access to many of the functions contained in the menu. The toolbars shown here is just one arrangement with all of the toolbars activated. Of course, Windows provides the ability to undock or move each toolbar individually, so they may be positioned differently.

Run (Transport) Toolbar (with Motion/Capture option)

Time Shift

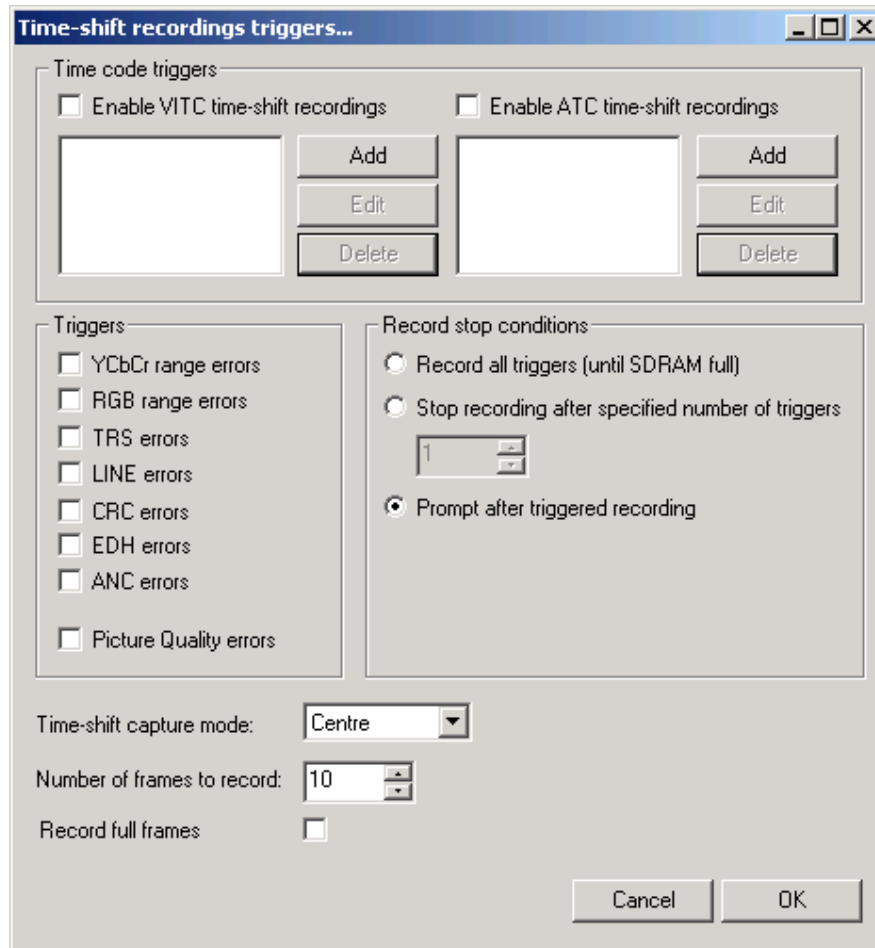

The first two icons are concerned with the Time Shift feature, which is only active if the Advance Option Package is present. Time Shift provides the ability to trigger a video capture only if a specified error condition occurs. Captured video can then be reviewed or stored to disk for later view.

Enter Time Shift mode and wait for a trigger

Configure Time Shift mode. This brings up the Time Shift dialogue box, which is shown below.

A Time Shift recording can be triggered by one of the trigger conditions shown in this dialogue box. It can be based on reaching one of several given VITC or ATC timecode values, or on a specific error condition, such as a CRC error occurring.

In all cases, it is possible to remain in Time Shift mode, waiting for the next trigger, and continuing until the RAM is full, or to capture a specific number of triggered events, or to only capture once, then ask the user whether to continue.

Since data is always being captured into a circular buffer, after a trigger it is possible to retrieve frames prior to the trigger event. In this way, the grabbed clip can be arranged with the trigger frame at the start, middle, or end of the clip.

Frames can be captured with only the active video being stored, or with the entire video raster also being stored, by selecting the 'Record Full Frames' control.

Sequence play controls

Jump to start of the Clip/Sequence

Move back in the clip by one frame

Play the clip backwards. Note that this reverses the order of the frames, but not the fields.

Stop playing the sequence

Play the clip forwards

Move forwards in the clip by one frame

Jump to the end of the clip

Enable loop mode for sequence play

The Frame box with drop down selection lets you select an individual frame from the sequence for immediate display.

The speed box with drop down selection lets you choose a playback speed for the sequence. This can be real time, quarter speed, half speed or double speed.

The Record Frames box is where you specify how many frames will be captured during a Time Shift capture. This is a duplicate of the control on the Time Shift configuration dialogue.

Source Toolbar

OmniTek XR has two different Source toolbars. The above toolbar is active for the basic product, and applies to single link sources. The block diagram indicates major functional blocks in XR.

The Source toolbar is used to select whether input A or input B is active, and to select whether the OmniTek XR Analyzer module is directly looked at the serial input, or the output of optional Motion/Capture module. Similarly, the analogue monitor output can be set to reflect what the analyzer is seeing on the serial input, or can look at the motion/capture module. The serial output can be configured in the same way.

Source Toolbar (Dual Link Option)

This version of the Source toolbar replaces the original toolbar when a Dual Link video format is selected. This is only accessible if the Dual Link option is included on the system. When you switch back only the Video Standard toolbar to a single link source, the standard Source toolbar reappears.

When operating in dual link modes, the source to the analyzer module, the monitor output and the serial outputs all must be the same, so all either look at the internal test pattern generator (or Frame-store), or they all look at the serial input.

In Dual link, there are two modes of operations. It can either operate in full dual link, or it is possible to select the 'Single-link' button, and then switch between using Link A or Link B as the input. This mode exists for ease of switching between single and dual link formats. However if you are using single link for extended periods, it is recommended to switch to a single link video format on the Video Standard toolbar, as in this mode there is a slightly extended functionality.

Whilst in Dual Link, and assuming the Motion/Capture option is also included, the source to the waveform monitor can be selected between the internal pattern/sequence generator (Frame-store option), and Serial input.

Main Toolbar

The main toolbar contains controls to open the various windows used by the application, plus quick access to some commonly required functions.

The first icon opens the Generator control window, and is only present with the Motion/Capture option.

The red 'triangle' icon is used to open the Capture dialogue, to capture from the single or (optional) dual link input.

The icon to the left of the red triangle icon is used to load an image or sequence previously saved.

Full details of the controls within this window start on page 53 of this manual.

The next icon opens the mini-pic window, where you can see a representation of the incoming video, or captured sequence. This is particularly useful with video formats with a particularly low frame rate, which cannot normally be display on conventional HD monitors.

This icon opens the waveform window. The waveforms will be displayed in the form set using the extended control surface within the waveform window, which is independent of the actual format of the incoming video. The waveform window has menus to configure how the window contents are displayed. This is detailed on page 45.

This icon opens the histogram window, which permits detailed analysis of colour gamut information. See page 40 for details of the histogram window.

Enable/Disable the Vectorscope. The Vectorscope can be used independently of the waveform mode.

Like the waveform window, the vectorscope window contains menus to let you configure the display.

Enable/Disable the data view. This is a window containing sample number, and the data values of that sample number, on the current line, plus samples earlier and later in that same line. The sample and line numbers are determined by the position of the main cursor, which may be changed by clicking in the mini-pic or trace windows, or by using the fine control buttons on the toolbar. The total number of pixel pairs being displayed is determined from the Options menu of the dataview window. The value can be adjusted from 1 to 512 samples. The dataview window is scrollable, so you can check video data over a large portion of a video line without moving the cursor.

The data shown will be the actual data on the serial inputs. With the optional Dual Link upgrade, column headings are displayed which reflect the data format set in the Engineering menu. Dual Link data can be RGB or YUV.

The data view window will display six columns of data when set into dual link mode, or three columns when in single link mode.

The contents of the Data View window may be saved as a .txt file. (See the section on window menus on page 45). The file will include all the data within the scrollable window, so if the window is set to contain 100 samples, then these 100 samples will be saved in that txt file. The data will be stored in the file in whichever base they were being displayed in. I.e. the file will contain decimal, hexadecimal or binary values as selected for the window.

The contents of the data view window are colour coded. In all cases, the text remains white, but the background colour changes to show the nature of the data.

Green indicates pixel is within active video

Blue indicates pixel is within a TRS packet

Purple indicates pixel is within an ANC packet

Light grey indicates pixel is within horizontal blanking

Black indicates pixel is within vertical blanking for field 2

Dark grey indicates pixel is within vertical blanking for field 1

Red indicates a data range error (i.e. video data outside the range that has been set on the Engineering menu). With Dual Link products, there is no guarantee that this range is valid for the actual data type on the serial inputs. Hence it is important to ensure that the data ranges expressed on the Engineering menu reflect the type of data you are expecting.

Like other windows, the data displayed can be configured from the drop down menus contained within the window.

Enable/Disable the video status window. This window lets you view the status on various video parameters, and provides controls to enable counters for various error conditions. For example, you can count the number of CRC or ANC errors from a given time.

For each given error type, you can display the errors in the following formats.

Display the word ERROR on a red background.

Display a continuous count of the number of errors since the last reset.

Display an error rate in errors per second.

Display the time since the last error or since the error count was last reset, as appropriate.

In all modes, the background colour indicates if errors have been detected, with red indicating an error.

The contents of the Video Status window are described in the section on OmniView Video Checking Features, starting on page 48.

Enable/Disable the audio status window. This window displays information about the current audio status, and also contains the PPM meters. The PPM meters can display audio levels from two of the four available audio groups. The choice of which two audio groups is made from the Analyzer menu. The graticule can be changed using the menus on the window. Refer to page 48 for details.

This icon opens the logging window. The window shows a live display of data that can be logged. This is fully described in Appendix A2, together with other related material.

Open the cage generator (safe area/title) dialogue box. For a full description of this, please refer to page 46 in this manual.

This button opens or closes the 'Region of Interest' control window, which is described on page 43.

This button opens a drop down menu that lets you switch between single line view, multi line view, and sweep mode. This control duplicates the drop down at the top of the Region-Of-Interest window, described on page 43.

Open the Engineering menu – which is described in full starting on page 17.

Crosshair Toolbar

Next to these controls, we have the controls for the main cursor position.

These show the sample number and line number that the cursor is positioned over. Using the mouse, you can click in the mini-pic to position the cursor, and then use these boxes to make fine adjustments. For interlaced standards, you can switch fields using the '1' and '2' boxes. For progressive standards, these buttons have no meaning, and are grayed out.

You can also use the sample number box to view horizontal blanking. Select horizontal magnification, and then increment the sample number such that the sample is outside of active video. The trace windows will scroll to show that sample position in the blanking area. This will let you view audio or ancillary data that may be present, if the 'TRS Pass' selection is on – see the Analyzer menu.

The 'top' and 'bottom' buttons position the cursor on the top active line, or bottom active line of the field/frame.

The 'left' and 'right' position the cursor on the first or last active pixel of the current line.

The crosshair can appear on the outputs by selecting from the drop down menu. This can be selected as either the analog (monitoring) output, the serial output, or both outputs.

Cursor Toolbar

Below these, we have the measurement toolbar.

This lets you enable either time measurement, or amplitude measurement cursors. For each cursor type, two cursors may be placed in the trace windows, and moved about to take measurements. Time values are displayed in microseconds, whilst amplitude values are a relative difference between the two cursor positions.

Click in the cursor 1 or cursor 2 box, to let you control which cursor you are affecting when subsequently clicking in a trace window. The active cursor appears as a solid line, whilst the other cursor becomes dotted. The colour of these cursors is determined in the Options/Cursors menu selection in the waveform window.

To move the cursors as a pair, lock the cursors together by checking the 'Track' box.

Please note that it is not possible to control the main cursor by just clicking a new position in the mini-pic, when either of the time or amplitude measurement cursors are active. The cursor function box must be set back to None, to regain mouse control of the main cursor. However, it is always possible to move the main cursor by editing the pixel and line values in the crosshair position toolbar.

Video Standard Toolbar

This small toolbar only has one function, which is to change the video standard.

There are two versions of this toolbar. The above version is present in a basic XR system, whilst the version shown below is present if the option Dual Link module is present.

Using the drop down menu is identical to selecting the video format from the Video section of the Engineering dialogue'. The video lock reference is unchanged. If the 'Auto detect' button is pressed, then the video lock will automatically switch to 'serial lock'. If auto detect is subsequently cancelled, the unit will remain in serial lock.

For dual link systems, clicking the 'Dual-link' button forces the auto detect circuit to assume it has found a dual link input based on whatever format it finds on Link A or Link B. The drop down menu is also extended. All the single link formats are listed as for the regular XR system, but underneath these is the complete list of supported Dual Link formats, including the 2K formats.

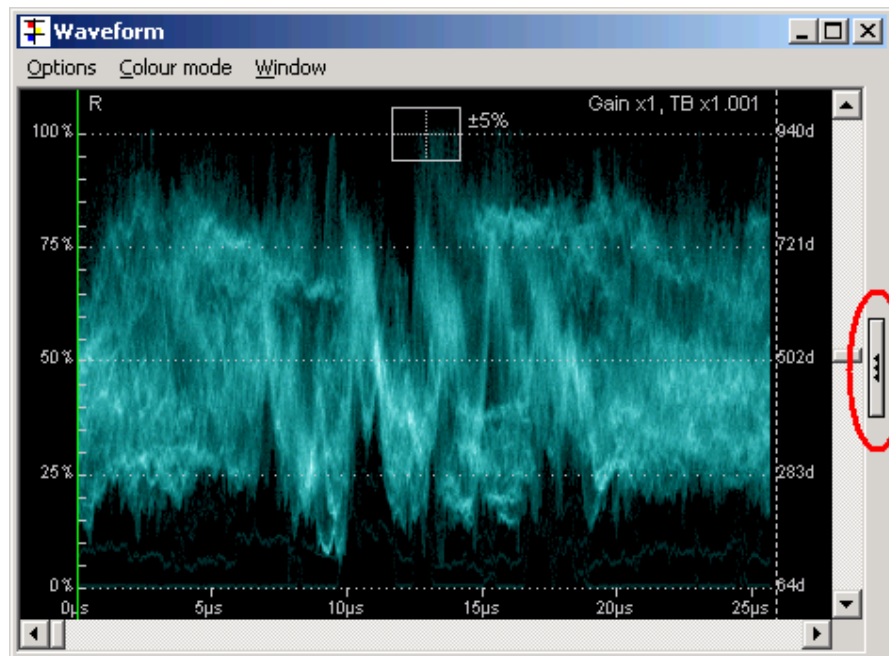

Note that clicking on the 'Dual-link' button only changes the action of the Auto detect circuit. It does not of itself cause the unit to switch into, or out of, dual link mode. You must look at the video standard specified in the drop down box to see if you are currently running in a single or dual video format.

4 XR Windows

Waveform Window

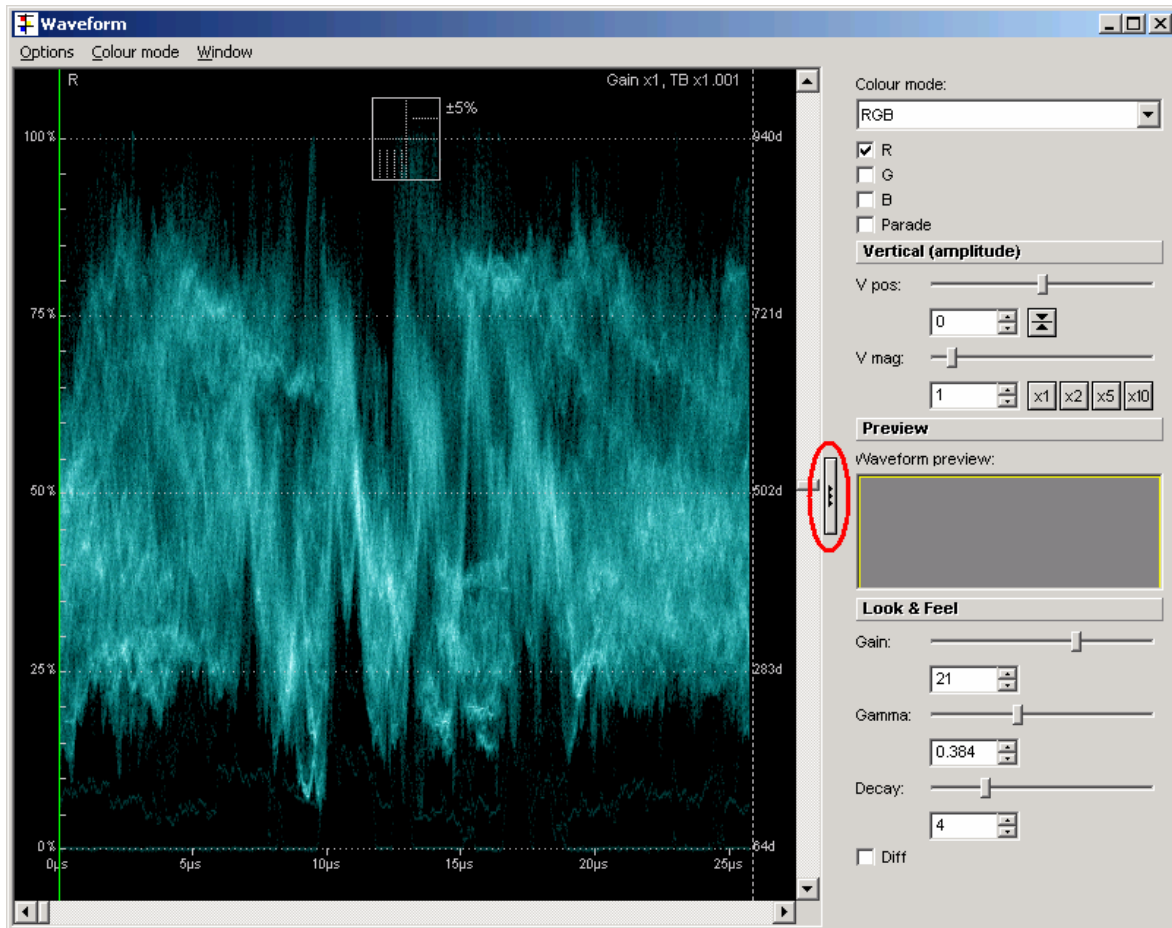

OmniTek XR has extremely powerful and flexible waveform displays. The necessarily means that there are more controls over waveform display than in conventional products. This section describes the full set of waveform controls that are included as part of the waveform window.

The waveform window can operate in one of two distinct modes, depending on whether the complex set of controls for the window are visible or hidden.

The view above shows these additional controls being hidden, but highlights where to click to reveal the window controls. The more commonly used controls are also accessible from the 'Colour Mode' menu, on the waveform window.

If you click in the highlighted section (and grow the window so that you can see all of the details), you see the following window.

Clicking in the highlighted area this time will hide the waveform display controls, and revert to the previous window.

There now follows a description of the waveform display controls.

OmniTek XR can operate the waveforms in a variety of different fundamental modes, which are selected from the 'Colour mode:' drop down control. These are –

YCbCr	in the original format as per the serial input
YCbCr (SD)	displayed on graticules that match regular SD data
YCbCr + composite	As YCbCr but also showing a composite display created from the component data
YCbCr + composite (SD)	As YCbCr (SD) but also showing a composite display created from the component data
Y + RGB	Shows luma plus the RGB component data
RGB	Standard RGB display
RGB + composite	RGB display also incorporating the same composite display from the other modes
Composite	Only shows the composite waveform
Bowtie	Shows a standard Bowtie display

In all modes, selector boxes appear for each item included in the waveform display, so that items not required need not be shown. The remaining items automatically stretch to fill the space when an item is removed. The waveforms can all be display as full width, with each different component stacked vertically, or in a standard parade form.

The vertical position of the waveform can be adjusted in conjunction with the vertical magnification control, to zoom in on particular portions of the waveform. However this

can be done far more easily by right click and dragging over a portion of the mini-pic display. The chosen area is highlighted on the mini-pic.

The section of the mini-pic marked out is used for waveform generation, so you get waveforms zoomed into that area. To revert to the normal display, you must double click with the right mouse key, over any portion of the mini-pic display. Note that when the area is marked on the mini-pic, the vectorscope also only displays vectors based on information in this area.

Note also that the technique of marking out an area on the mini-pic also works in exactly the same way whilst in full screen modes.

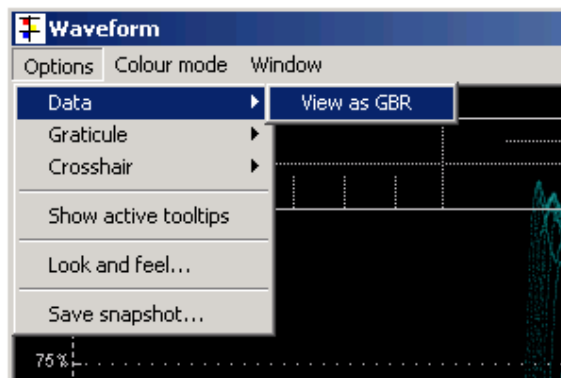

You can also adjust the sliders on the waveform window controls, or enter specific numbers in the numeric entry boxes. For magnification, boxes are available to select various standard levels of magnification.

If the magnification is used, the 'Waveform preview:' section shows which section of the video is being used for waveform generation.

The 'Look & Feel' controls can be used to fine tune the gain, gamma curve and decay of the waveform traces. However these are automatically adjust to suit variable levels of gain etc, so these controls are not normally used.

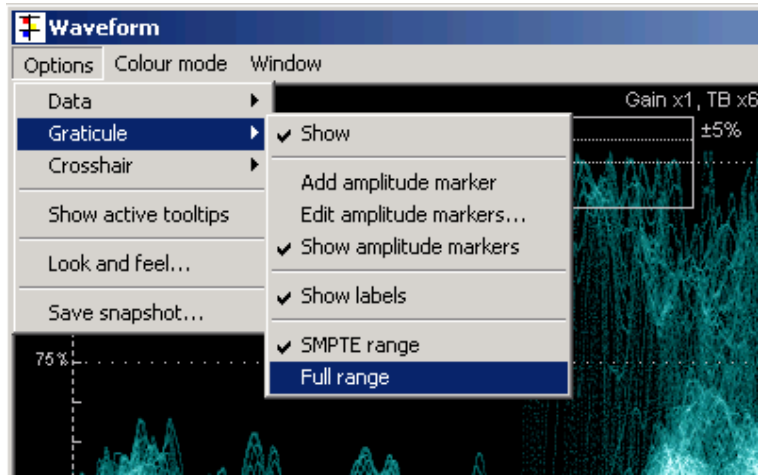

Other controls to affect the waveforms can be found from the three drop down menus in the waveform window.

Options Menu

From the options menu, you can adjust a few specifics of how the waveform traces are displayed.

For RGB type displays, the components can optionally be re-ordered into the GBR order.

The graticule lines can be displayed or hidden, and the graticule text labels can also be displayed or hidden. Amplitude markers may also be overlaid onto the main graticules. These are horizontal lines that can be used to mark out important levels. It is possible to define multiple markers, and change which is displayed, or to display several at a time.

Note that the units for both axis of the graticules are customizable, using the global selection on the File/Preferences menu selection. See page 10 for details. As an example, this can switch between decimal or hexadecimal values, or into a mV scale.

Lastly graticule calibration can be based around the standard SMPTE range of 64 to 940/960 (expressed as decimal, in 10 bit format), or alternatively around the full range of 0 to 1023 (again decimal, 10 bit). Full range video formats are particularly useful in Dual Link when using RGB signals. For example, Thomson Viper cameras generate RGB in the range 0 to 1023. Other cameras generate RGB in the range 0 to 940, so having the variable calibration means the waveform monitor can be correctly set to suit.

The visibility of the crosshair can be toggles. The crosshair appears as a cursor at a given horizontal position on the waveform. If several components are displayed in the waveform, then the cursor appears in the same place on each component. The position of the cursor can be changed by clicking within the waveform.

Active tooltips causes a small box to follow the mouse pointer providing the X and Y coordinates of the point under the pointer.

The 'Look and feel' menu selection opens a dialogue box that permits customization of colours of various items.

The Look and feel dialogue can be opened from the Options menu on each of the Waveform, Vectorscope, Histogram or Mini-pic windows. The default page that is active is chosen depending on which window you opened it from.

For the waveforms, the colour of the graticule, and of each different waveform element can be individually chosen. When the waveforms breach the thresholds for valid video, (specified in the Engineering dialogue, details on page 20), the waveforms can be coloured in a different colour. Again these 'error' colours can be specified uniquely for each different waveform type.

The CRT emulation applies a special filter to the trace data to emulate the look that is typical of analogue CRT based waveform monitors.

The cursor selection lets you change the colour of the measurement cursors, which can be used to measure time or amplitude between two points. The measurements are done using the cursor toolbar, which is described on page 33. Similarly the crosshair colour is configurable.

All of the look and feel choices here will directly affect the waveforms displayed within the Windows environment. They will also affect all waveforms included in full screen mode, **unless** specific look and feel settings have been **assigned** to chosen full screen modes. To find details on assigning, and unassigning look and feel settings to full screen modes, please see page 16.

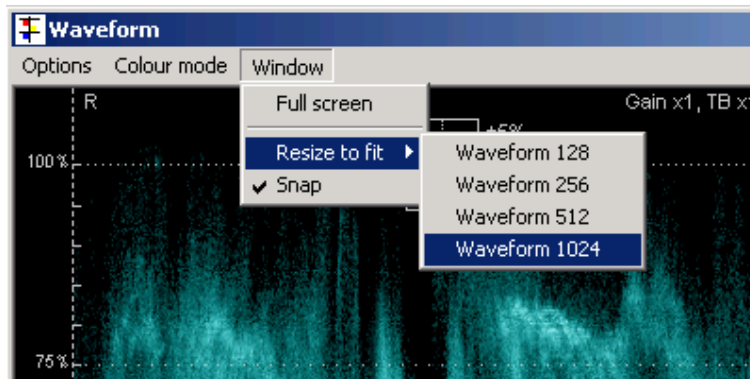

As the last menu choice, 'Save snapshot...' takes the currently displayed waveform image, and writes it to disk as a bitmap file. The user is prompted to enter a filename during the save operation.

Colour Mode menu

This lists the different forms of waveform display that exist. This duplicates the Colour Mode section on the waveform additional controls section, described above. The controls are duplicated for user convenience. Note that although you can select each mode from the menu, you will still need to access the controls within the window to change from parade to vertical format, or to select specific components for display.

Window menu

The window menu lets you directly enter Full Screen mode displaying waveforms. Press the ESCape button to return to normal windows display, or to subsequently re-enter Full Screen mode,

The 'Resize to fit' option changes both the waveform display, and how the waveforms are generated. The video processing hardware can generate waveforms in one of four resolutions. At the highest resolution, a single LSB (out of 10 bits) will cause a viewable change in the waveform. This provides the best possible quality to see maximum detail. However in some applications, a lower resolution is quite sufficient. We recommend selecting the size that gives waveforms of a screen size nearest to your requirements, and then stretch the window to the exact size.

Histogram Window

The histogram window displays colour histograms provided a detailed and accurate method of assessing colour gamut. Unlike traditional displays that indicate a signal is out of gamut, but little else, the colour histograms provide a great deal of information as to how out of gamut the signal actually is.

The histogram window, like the waveform window, contains a section of controls which can be displayed or hidden on the right hand side of the window. Please see the above section on the Waveform window for details of revealing the window controls. Again like the waveform window, the most commonly used controls are available from the Colour Mode menu.

Like with the waveform window, the top control in the right hand bar is the most important, and controls the format of the histograms. The available modes are

- YCbCr Histograms are generated in YCbCr space
- YCbCr (SD) As above but after conversion to true SD levels
- RGB Histograms are generated in RGB space
- Composite Histograms are generated in Composite colour space.

In each of the four modes, check boxes appear so that a subset of the items can be displayed if required. Items may be displayed stacked vertically above each other (as shown here) or in parade form.

The X position and X magnification sliders may be used to zoom in on a portion of the waveform. It is also possible to enter numbers for position and gain into the boxes, or click on the x2, x4 etc buttons.

The vertical range sets the scale of the graph, and can be adjusted to suit your exact data, but clicking the Auto button will produce a suitable scale very easily. For most data, the best results will be obtained by clicking the 'Log' button, which applies a logarithmic scaling to the vertical axis (before pressing the Auto button).

From the Options menu, you can open the Look and Feel configuration dialogue, in exactly the same fashion as for the waveform window. This lets you specify the colour for each different possible Histogram element, including the Graticule and the cursor.

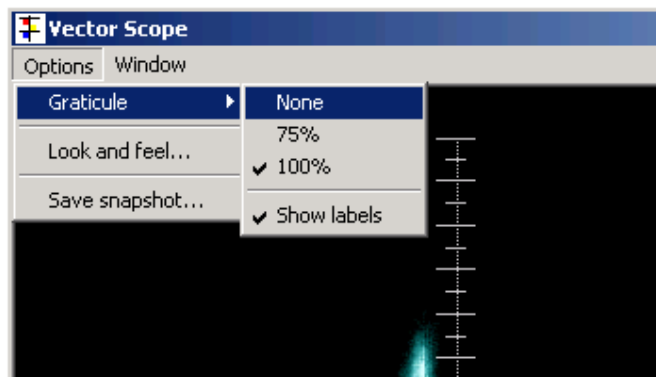

Vectorscope Window

The vectorscope window, like the waveforms and the histograms, has a section of controls that can be revealed and hidden. However all of these controls for the vectorscope are automatically adjusted as the region of interest is changed. Accordingly these controls will only be required very occasionally.

The Look and Feel controls adjust the filtering controls applied to the module creating the vectorscope display. The Gain control affects the brightness of the vectorscope image, whilst the Gamma of the display can also be varied. Finally the length of the persistence on the display can be adjusted with the Decay control.

Other important controls are available on the menu bar of the window.

The Graticule controls let you change between a 100% graticule and a 75% graticule, or to hide the graticule, or separately hide the graticule labels.

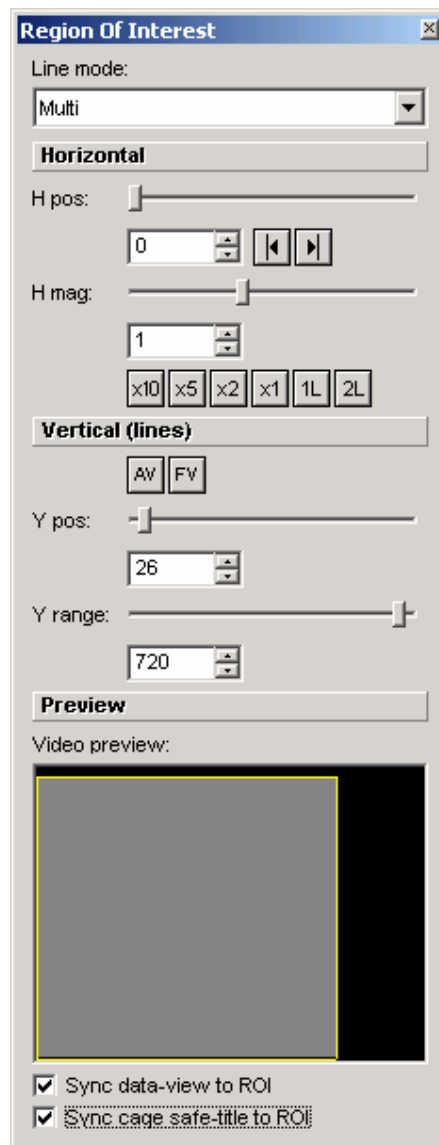

The Look and feel selection opens the common dialogue used to separately specify the colour of the graticule and the colour of the data. You can also enable CRT emulation.

'Save snapshot' will take the current vectorscope data and write it to a named bitmap file.

On the Window menu are controls to resize the vectorscope display to match the resolution in which it is being generated. These work in a similar fashion to these controls on the waveform window.

Region of Interest Window

The Region of Interest window controls some of the less required function, as most of the controls can be achieved by other means. Alternative ways of control will be described along with the functions on this window. These controls are global in that they affect the portion of the video image that is used to create the waveforms, the vectorscope, and the histograms. Note that the dataview display is unaffected by these controls, as it always shows the exact incoming data based around the current cursor position.

The top control is the most important one, and lets you change the waveform view from all lines (multi), to single line, or to sweep mode. This control is available by clicking on

the line mode button  on the main toolbar.

The horizontal and vertical controls let you narrow down the area of interest.

The default waveform position has pixel 1 at the left of the display, and the last pixel on the right of the display. It is possible to scroll the view of the waveform around, which provides a useful means of examining blanking data. This can be done with the 'H pos' slider. The image can be magnified using the 'H mag' slider, or numeric data entry, or by clicking on the 'x10', 'x5' or 'x2' boxes.

You can select a single line or two line display with the '1L' or '2L' boxes. You may need to select the single line mode in conjunction with these controls, depending on exactly what you want to see displayed.

Similarly, it is possible to select only a given vertical portion of the video image to create waveforms, using the 'Ypos' and 'Y range' controls.

The AV and FV buttons switch the waveform display between being restricted to just the active portion (AV), or the full raster (FV). These two buttons will only be visible in certain display modes.

There is another way of selecting a specific portion of the image for waveform generation. By right click and dragging with the mouse over the mini-pic, in either the windows view, or the full screen view, you can define an area. This defined area will be used for the waveforms, the vectorscope and the histograms. The magnification controls are automatically adjusted for the best display.

Having defined an area, you can move the area about over the video by clicking and dragging with the middle mouse button. Finally, double clicking over anywhere in the mini-pic, with the right mouse button, will revert to a full view over the entire frame.

The 'Sync data-view to ROI' control means that when you define a region of interest on the mini-pic, the data view jumps to display the centre line within the defined region. If this control is cleared, the dataview continues to show the values for the original area, which may be outside of the defined region.

It is possible to click and drag to create a custom Safe Title (see Cage Generator on page 46). By selecting 'Sync cage safe-title to ROI' the area defined in the Region of Interest is automatically applied as the area used for a custom safe title.

Mini-Pic Window

The mini-pic window has some important options available on its menus.

The Pulse/cross mode delays the video by half a frame both horizontally and vertically, to emulate the HV delay mode of CRTs. This may permit a clearer view of data adjacent to blanking. This mode may be more useful if the 'TRS Pass' mode is also enabled, from the Analyzer menu of the main application.

The display of the mini-pic defaults to normal, full colour mode. When using the XR in a colorist environment, where brightly coloured displays can be a distraction for the colorist, it may be helpful to switch the mini-pic into the monochrome mode.

The mini-pic can also be switched into a blue or green mode, whereby the blue (or green) data is applied to all three channels. This can be very helpful in looking for noise, or perhaps for looking for macroblocks, which tend to be more pronounced in the chroma channels over the luma channels, especially in HD.

Show Closed captions is only useful if the incoming material (or test sequence) contains closed caption source, and if the correct source has been selected, which is also done from the Analyzer menu of the main application.

The aspect ratio of the mini-pic can be changed from its default settings to preset values, or to a custom value, or may be forced to follow the Wide Screen Signaling values that can be contained within PAL video.

The display of the crosshair on the mini-pic window can be enabled or disabled.

Active tooltips shows the mouse position in pixel sample number, and video line. For interlaced video formats, the line number will be displayed based on the field selection that has been made on the Crosshair toolbar, as described on page 33.

The Look & Feel brings up the common Look and Feel dialogue, directly onto the mini-pic settings page. You can select the colour of the crosshair, and independently the colour of the cursor.

Lastly, you can save a snapshot of the currently displayed image. This is saved as a .BMP file.

Window Controls

The waveform window, the vectorscope window, the data view window, the audio meters window, and the mini-pic window all have drop down menus to configure how the window contents are displayed, or the window manipulated. Not all windows have exactly the same controls, but the following section should cover all of the available features.

The windows all have an 'Option' menu. Depending on window, this will have the following selections.

Data	Change from RGB to GBR format.
Graticule	Enable the display of graticule Show graticule labels Specify graticule as SMPTE range, or full range. Choose graticule as 75% or 100%, for vectorscope Choose calibration for different PPM scales, for audio levels
Crosshair	Show crosshair
Aspect ratio	Choose aspect ratio for mini-pic as one of a selection of standards, or choose custom aspect ratio
Show Tooltips	Gives line and sample number of point under cursor.

The windows also all have a 'Window' menu. This provides the following possibilities.

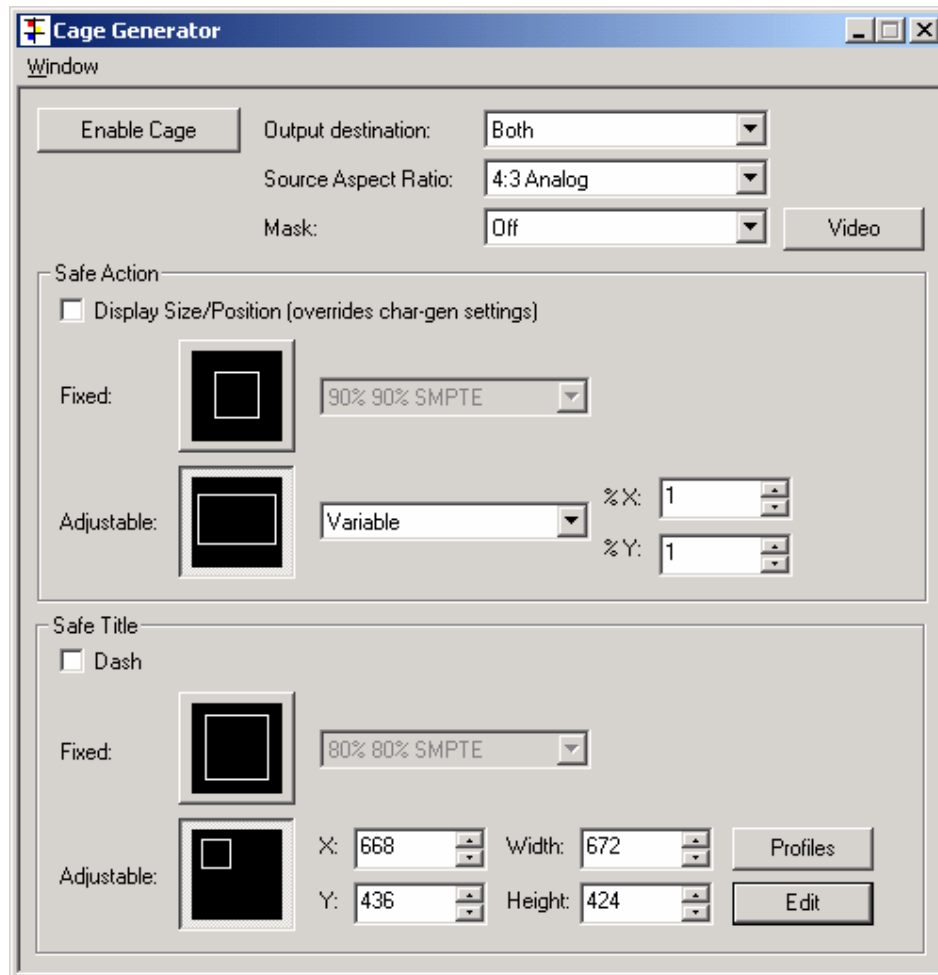

Full Screen	Select this and the chosen window data will be displayed in a full screen mode, without any windows artefacts present, such as toolbars, menus etc. Press Escape to return to the standard display.
Resize	Select this to change the window size to the default minimum size to suit the data being displayed.
Snap	If this choice is enabled, windows snap to points on a grid as you move them around, which sometimes makes it easier to line them up as you require.
Stretch	By default as windows are resized, the data remains the same, with the extra space padded with black. By selecting this option, the data contents are stretched to full the window, although still maintaining the original aspect ratio.

Cage Generator

OmniTek XR contains a cage generator. By selecting the cage icon  the Cage dialogue appears.

To enable the display of a cage, press 'Enable Cage'. To enable masks, select a mask type from the drop down box. The mask will only be shown if Enable Cage is selected.

The OmniTek hardware contains two separate cage generators, one for safe action, and one for safe title. Either can be used in the fixed or adjustable mode.

If you are displaying both safe area and title together, it may be desirable to make the safe title lines dashed, using the check box, so that you may distinguish the two.

It is possible to have the size and position of the safe area box shown on the main outputs, again by checking the relevant box.

The masks key out the video in the selected area, replacing it with black. Masks may be enabled either inside or outside of the safe area or safe title boxes. The video that is masked out is also removed from the error-checking module, so the masks can be used to reduce the area where errors are flagged. Alternatively, by pressing the 'Video' button, the keyed out area is replaced with the currently selected image or sequence in the Generator window (if Motion/Capture options are present).

The safe title box may be positioned by adjusting the X and Y values. However, it may be more easily positioned by clicking the Edit button. You can then click and drag over a representation of the current image. The box position can be fine tuned using the X & Y boxes afterwards. The settings can be saved. Click the Save icon to the right of the

'Profile' box. If there is a name shown in the profile box, then your settings will be saved to this 'file'. If it is blank, a dialogue box appears to let you enter a new name. Once you have several names in use, they can be selected by using the drop down arrow to the right of the profile box. Hence if you have several settings that you regularly use, these can be stored and recalled, without having to re-enter them. Note that these settings are saved into the registry, not as actual files on disk.

Whilst you are using the 'Edit' feature, the main mini-pic will be turned off. This is because the Edit dialogue is using the same mini-pic element to create the image.

The safe title box may be positioned by adjusting the X and Y values. However, it may be more easily positioned by clicking the Edit button. You can then click and drag over a representation of the current image. The box position can be fine tuned using the X & Y boxes afterwards.

It is also possible to save custom settings as 'profiles'. Once the Profiles box is open, click 'Edit Profile' to create a new profile, which is stored automatically. You can then select from numerous named profiles.

5 Video Checking Features

Introduction

OmniTek XR has the ability to display real-time status information for audio and video data, and to detect and count various types of errors. Status information and error counts are displayed in two status windows, one for video and one for audio.

Video Status/Error detection

The Video status box has two main modes of operation. This is Report View, and normal view. In report view, there are no buttons on the Video Status window, so it only reports information. In the normal view, there are reset buttons for all error counters, error mode buttons, and alarm enable buttons, together with a global reset, global error mode and global alarm enable mode. Selecting 'Report View' from the Options menu toggles between these two modes.

The Reset error count menu selection lets you reset all counters, or specific ones as required.

The number of errors since the error counters were last reset is displayed in the video status box. For each error condition, there are various display modes available. You can cycle through the available options by repeatedly pressing the mode button. Note that the mode button looks slightly different depending on the current mode. This function is duplicated by the 'Toggle error count states' menu selection.

Display modes are -

Show the total number of errors. The number will be displayed in green whilst the count is 0, and be red if there are errors.

Display the word 'Error' in red text for 0.5 seconds after an error is detected, then revert to showing 'OK' in green text.

Display the elapsed time since the last error. The text will be green if the error count is 0, and red otherwise.

Display the number of errors detected per unit of time. The unit used for time will vary depend on the actual error rate.

Clicking the red **R** resets the individual error count. Alternatively, you may click the red **R** at the very bottom of the window to reset all error counters.

The following information is displayed in the Video Status box

General video status parameters

- Input standard - Shows what standard has been detected (if in auto input detect), or shows the standard that the unit has been set to (if standard has been manually set).
- Serial digital input - present & in correct standard, present but in an incorrect standard or missing

The colour of the text of the status message, as well as the text are used to provide status information. The messages have the following meanings.

OK Serial input is good, and **is** being used as lock reference.

OK Serial input is good, but **is not** being used as lock reference.

Missing Serial input is not connected, and **is** being used as lock reference.

Missing Serial input is not connected, and **is not** being used as lock reference.

Wrong Format Serial input is connected, and **is** trying to use as lock reference, but is failing – perhaps because it does not match the current standard.

Wrong Format Serial input is connected, but is either bad, or does not match the current standard. The serial input **is not** being used as lock reference.

- Picture motion - moving/frozen

- The warning message can occur instantly, or after the condition has occurred for greater than a set period. This can be adjusted in the Picture section of the Engineering dialog.
- Luminance content - present/chroma only
- The warning message can occur instantly, or after the condition has occurred for greater than a set period. This can be adjusted in the Picture section of the Engineering dialog.
- Chroma content - present/monochrome
- The warning message can occur instantly, or after the condition has occurred for greater than a set period. This can be adjusted in the Picture section of the Engineering dialog.
- Analogue reference sync - present & in correct standard/present but in an incorrect standard/missing.

The analog reference uses text in two colours to indicate status in the same way as for the serial input.

Video Index parameters

- Active format - not present or description of actual format
- Coded frame - not present or description of actual format
- Component set - not present or description of actual format
- Sample structure - not present or description of actual format

Wide screen signaling parameters (SD only)

- Aspect Ratio - not present or description of actual format
- Enhanced services - not present or description of actual format
- Subtitles - not present or description of actual format
- Others - not present or description of actual format

Teletext Detection (SD only)

- Teletext information - present/not present

Closed Caption detection

- Closed Caption (ANC 608) - present/not present
- Closed Caption (ANC 708) - present/not present

Error Checking parameters

- CRC Check - Checks for valid CRC (EDH in SD). Counts number of errors since last reset. View calculates a new CRC value from the incoming data, and compares this value with the CRC value embedded in the data. If there is a difference, View will flag this as an error.
- Gamut check - checks the YUV data to see that it would be valid if converted into RGB space. The RGB valid range is programmable at both minimum and maximum thresholds. Counts number of errors since last reset. The range of valid values is set on the Video Engineering menu.
- Range check - checks the YUV data to ensure that it falls within the valid part of the range. For each of Y, U and V, there are programmable minimum and maximum thresholds. Counts number of errors since last reset. The range of valid values is set on the Video Engineering menu.
- TRS check - Checks for valid TRS data. Counts number of errors since last reset.
- ANC check - checks for valid checksums on the ancillary data. Counts number of errors since last reset.
- LIN check - (HD only) checks that the line number specified in the TRS packet agrees with the line number calculated internally. Line numbers are not included in TRS packets in SD.

All parameters in the Error Checking section have a simple line graph which shows the status of each parameter over the last few seconds. This is a thin line displayed under the error counter display. After resetting the error counter, the line is fully black. As time passes with no errors, the line is gradually

turned green. Periods of time when errors occurred are coloured red. Hence by looking at this line, you can see whether errors are in bursts, or periodic, etc.

Timecode Checking

The View module can check timecode on the serial input. The reader is configured using the Time Code page of the Engineering dialogue box, described on page 23 of this manual.

Where timecode is present, it is displayed at the bottom of the Video Status window, under the error checking lines. In SD it is possible to display VITC and ATC. Only ATC is available in HD.

As well as displaying timecode values, OmniTek XR monitors the timecode to ensure that it increments correctly from frame to frame. Each time that a timecode value is duplicated in adjacent frames, or is discontinuous from frame to frame, it is counted, and these count values are displayed in the Video Status window. There are separate counters for VITC and ATC.

ATC is a timecode packet, and can be loaded with LTC, VITC 1, or VITC 2. The choice of timecode type is set in the Timecode section of the Engineering dialog.

VITC detection parameters. (Vertical Interval timecode) (SD only)

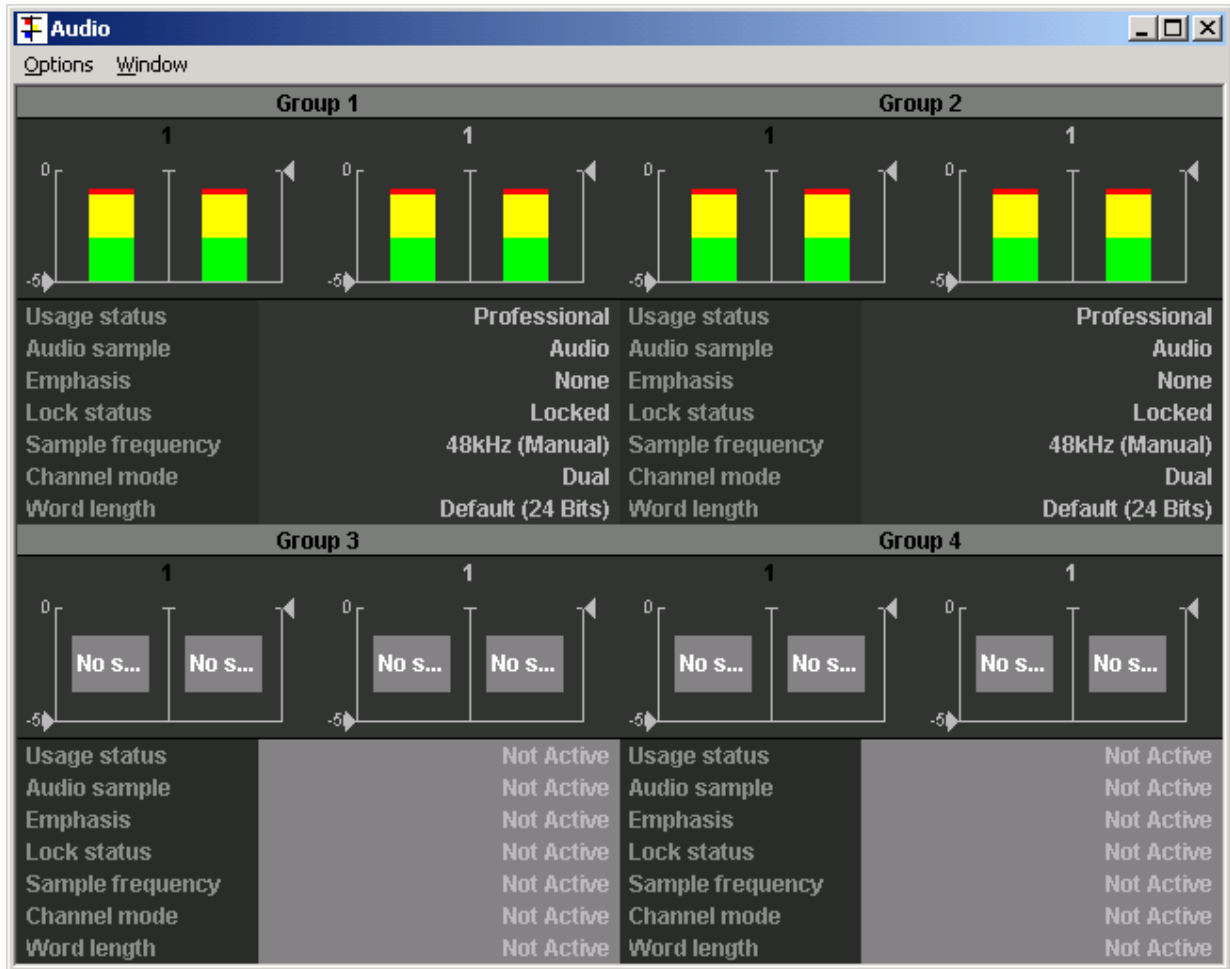

- VITC stuck frames. Counts number of stuck frames since last reset. (Looks for timecode not incrementing)
- VITC skipped frames. Counts number of frames skipped since last reset. (Looks at the timecode, and detects whenever a timecode value is missed)
- Actual display of incoming VITC timecode, or detection if timecode not present, or if corrupt.

ATC detection parameters. (Ancillary data timecode)

- ATC stuck frames. Counts number of stuck frames since last reset. (Looks for timecode not incrementing)
- ATC skipped frames. Counts number of frames skipped since last reset. (Looks at the timecode, and detects whenever a timecode value is missed)
- Actual display of incoming ATC timecode, or detection if timecode not present, or if corrupt.

6 Audio Checking Features

OmniTek XR monitors PPM levels of 8 of the total 16 channels of audio, and channel status information for all 16 channels, displaying the results in the Audio Status window.

For each audio group, XR firstly detects whether the group is enabled or not. If it is enabled, then the status information is display. If it is not enabled, none of the following will be present.

- Audio usage - Professional/Consumer
- Audio Sample - Audio/Data
- Audio Emphasis - None/50/15ms/CCITT J.17/Unknown
- Lock status - Locked/Unlocked
- sample frequency - detection of audio sample frequency, which is one of 32 kHz, 44.1 kHz, 48 kHz, or unknown
- Channel mode - Dual/Single/ "Primary/Secondary"/Stereo/Unknown
- Word length - default/16 bits/18 bits/19 bits/20 bits/22 bits/23 bits/24 bits/user/unknown
- Channel status - for each individual channel out of 16, we detect whether there is data present or not. If present, we detect if valid or not. If valid, we detect if the audio has exceeded programmable maximum or minimum thresholds. On the GUI, the channel status is indicated by colour coding.

Finally the audio levels are monitored and displayed. The audio levels are compared in real time to the thresholds configured in the Engineering settings (see page 22 for details), and if any of the monitored channels exceeds the peak level, or reaches the silence level, a red box appears over the ppm display, showing either 'Silence' or 'Peak'.

Please note that the Motion/Capture option for XR does **not** generate audio signals.

7 Generator Window

With the Motion/Capture option, the product has a Generator window, providing access to those functions required for saving and loading data. The contents and operation of this window is described here.

File Menu

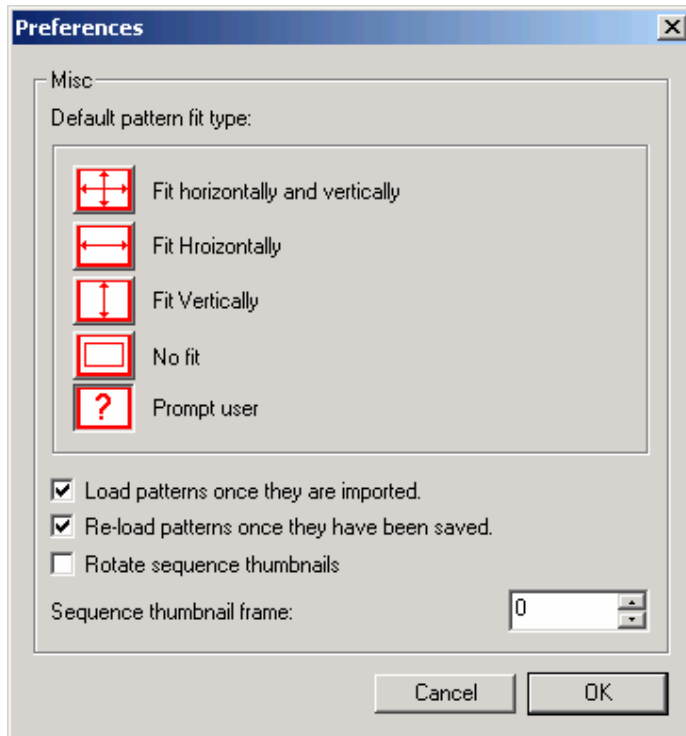

This lets you load and save configurations, where a configuration is a set of images and sequences. Note that you cannot use these choices to load individual images, as this is done from the Source menu.

This menu also lets you specify your Preferences for file loading.

Every time an image is loaded, its size is compared with the current video format. If it exactly matches, the image is loaded. If not, then the 'Default pattern fit type' is considered. This lets you specify a default action to take when loading images. One default action is to always pop up a dialogue box asking for a resize choice. The other options specify a default resize choice that the application will follow.

'Load patterns once they are imported' lets you control actions within a Gen configuration. When a configuration is loaded, a series of files are loaded into the control window. If this box is ticked, the actual video data is also loaded into the OmniTek card video memory. This would be the normal option to choose. However if you frequently wish to change configurations, and only use an occasional image or sequence from each configuration, then it may be quicker to clear this box, in which case no images are loaded with the configuration. To then load just a single image or sequence, merely click on the thumbnail and it will immediately start to load.

'Re-load patterns once they have been saved' is included to better cater for multiple file formats. For example, if a frame of video is captured, it is held in the frame buffer in the native YUV format. If you then save the image to disk as a .BMP image, the data has to be converted to RGB. The YUV frame being displayed will no longer accurately represent the file that has been saved due to the conversion from YUV to RGB. Ticking this box always forces the image to be reloaded. In this example, the RGB file would be loaded, converted into YUV and displayed. Although the image is back in YUV format, there would normally be significant changes to the colour information with respect to the original YUV image that was captured.

'Rotate thumbnail frame' refers to the thumbnail image that is displayed when a sequence is loaded. By default just the first frame of the sequence is displayed. By selecting this choice, the thumbnail changes from time to time to other frames within the sequence.

View Menu

The view menu controls aspects of how the window looks. It lets you turn off the toolbar and the status line if not required, and lets you chose a size for the image thumbnails. You can open or close the Playlist window, or switch between the Thumbnail view as shown above, or a text based list view.

Source Menu

The source menu is where you can load a previously saved image/sequence, or enter grab mode to capture from the serial input. Both of these functions are also available from icons on the toolbar, described later. You can also specify a Monitor folder. This is an area that can be continuously monitored for new files, with each new file being directly loaded once it appears.

Pattern Menu

The Pattern menu provides various options concerning how images and sequences are manipulated. Here you will find options to sort the images in various ways, or to save captured images, or to delete images from the configuration (but observe that this does not delete the image from disk). This is described in more detail on page 56.

Window Menu

The Window menu only has the option to enable/disable 'snap to grid' when moving the window around.

Toolbar Icons

The generator toolbar icons have the following functions.

New configuration

Open existing configuration

Save configuration

Import existing image or sequence

Capture data from serial input

Delete image or sequence from current configuration

Save current image or sequence to disk

Halt the import of patterns – useful if you start loading a sequence, then decide it is the wrong one.

Reload a selected image or sequence – if, for example loading was halted before it could complete

Reload all images and sequences.

Start file monitoring (only available if folder specified – see next icon).

Configure the file monitoring function – See page 60 for details

Enlarge the size of the thumbnail images (several sizes available)

Reduce the size of the thumbnail images

Toggle between thumbnail view and text view.

Open/close the playlist window. See page 61 for details on this function.

At the bottom of the Generator window there is a simple status display that displays the total memory available to store images, plus the amount that is used, along with a bar that gives a graphical indication of how much memory is used.

The numbers used are calibrated in frames, and hence will change depending on the current video standard.

If the Advanced module is present, then two sets of numbers are used, separated by a 'slash'. The number before the slash is the number of frames if the frames are video only, and the number after the slash is the number if the frames are video plus all blanking data – ie frames in the OmniTek RVF format.

Pattern Creation

Test patterns with the Motion/Capture option are one of two types – frames, and sequences.

Frame based patterns

These are stored as individual frames, so that a picture captured with a digital camera, or an image generated in a graphics application could be used. Images can be in a variety of standard image formats, (jpg, jpeg, gif, yuv, yuv10, bmp, dpx and cineon).

How to import Frame patterns

Selecting Import Image brings up the file selector dialogue box. Simply navigate to find files in one of the acceptable formats, select it, and click open. The image is then imported into the display window, and a subsequent single click will transfer it to the output.

Sequences

These are sequences of frame patterns. These are intended to be a sequence of adjacent frames captured from a video source. Once a sequence has been loaded into OmniTek XR, it can be replayed forwards or backwards, in real time or faster or slower, in a loop, as well as stepping through the clip frame by frame. Depending on standard, it is possible to play up to around 40 seconds of standard definition video.

Please note that XR is a frame-based product. This means that some field-based formats will sometimes give incorrect results. For example, if you play a field based sequence forwards, it will play correctly. However, if you play it backwards, the field sequence will not change, so the fields will play in the wrong order.

Similarly the image resizing is done on a frame basis. Hence if the images in a sequence consist of field images, and the sequence is resized on loading, then result may not be exactly as anticipated.

How to import Sequences

XR can load two main sequence types. The main approach is to load a .avi file. Note that .avi files can only be loaded if the relevant avi codec is installed into the Windows operating system. Codecs for common avi file formats are included in the standard Microsoft Windows installation.

It is also possible to load a sequence consisting of individual frames, as detailed below. There isn't a separate menu selection for loading sequences, as importing a sequence of frames is fundamentally the same operation as importing a single frame. Use the Import Image menu to bring up the file selector box. Instead of selecting a single frame, select multiple frames (use of the shift key when selecting with the left mouse button, will help here). Select OK, and the sequence will now load into memory.

For the frames to be recognised as a sequence, the file naming must obey the following rules.

Each filename must contain a fixed length number, so ensure that the smaller numbers are padded to the same number of digits as the largest number. The number can be anywhere within the filename, as long as the position of the number within the file name does not change. The number must increment contiguously.

The frames used can be any image types that XR accepts for single frame images.

Example of incorrect filenames.

Test_7, Test_8, Test_9, Test_10, Test_11, Test_12 – The digits are not of fixed length. Test_7, 8 and 9 need to be renamed as Test_07, 08, 09 etc.

Fred_08, Fred_09, Fred_11, Fred_12 – the numbers do not increment contiguously – file Fred_10 is missing, so the sequence will not load.

Tmp_02, 03_Tmp, Tmp_04, Tmp_05 – the position of the digits varies.

Once the sequence has been accessed, the first frame of the sequence will appear in the XR window. To actually load it into the output buffer, click on the image. Once the sequence has loaded, the transport control icons in the main XR window can be used. The transport controls are described on page 27.

Note that a long sequence, and in particular a long sequence of high resolution frames, will be slow to load.

Having loaded a sequence, you may use the 'Save As' option (right click on the image) to save it. XR supports saving sequences as .avi files, or as sequences of individual frames. Note that saving .avi files over the network is not supported. They can only be saved to the local drive. In conjunction with the Advanced option, it is possible to save captured frames in RVF format.

How to Grab Images (Motion/Capture option only)

From the pattern menu, select 'New Input'. The following dialogue box appears.

Three modes of grabbing are support, plus you can (optionally) select to either just grab the active video portion of the serial input, or to grab the entire data stream, including blanking, embedded audio, and ancillary data. This latter choice is made by clicking on the 'full frame' box at the top of this dialogue, and is only available if you have the Advanced option. More information is provided below.

Single – just grabs a single frame. Each time 'Grab' is pressed, a new single image is grabbed, over writing the image previously grabbed.

Repeated Frames – Grab between 1 and 10 frames per time. If you select 3, then you can press Grab three times, and each time an image will be grabbed.

Sequence - Select a length for the sequence (the maximum length will be determined by the standard you are in, and the amount of RAM fitted on your system). When you press Grab, the unit starts recording a sequence of images, of the duration previously set. This sequence may later be saved as a .avi file.

If you also have the Advanced Option on your system, you can select the "Record Full Frame", so that image/sequence grabs also grab the ancillary data, including embedded audio, and timecode data, closed caption data etc, and all of this data will be stored along with the image data. If this control is not checked, then only the active portion of the video is grabbed. See below for more detail on full frame images.

When you have finished grabbing your image(s), select 'Done'. You will be returned to the standard OmniTek desktop, with your grabbed images loaded into the Generator window. Any images you wish to retain will need to be saved. This can be done by right clicking on an image/sequence, and selecting 'Save As', in the usual fashion.

Full Frame Record/Playback (Advanced Option only)

The Advanced Option for XR provides the new ability to record or playback video, including the full video raster, such that all embedded audio, ancillary data etc, is captured with the video data.

Images and sequences grabbed as full raster may only be saved to disk in *.rvf (raster video file) format, and are saved in the usual way. Sequences are saved as multiple rvf files, all saved to the specified directory, with an incrementing number appended to the base file name that you specify. To load a rvf sequence for playback, simply select multiple rvf files with a contiguous, incrementing number in the filename.

The rvf file format is an OmniTek file format that contains a header, followed by the raw data from the serial bitstream. No processing is done on the video before it is stored, so the original colour space is preserved intact. Details on the file format will be made available to any interested parties.

The video data is not compressed in any way. This means that the RAM on the OmniTek card will hold fewer frames of rvf video as opposed to standard video. On the status line of the application, the number of free frames and number of frames used has been updated to contain two sets of numbers, separated by a '/' character. One number shows the number of frames in rvf format, whilst the other number shows the number of frames for standard video frames.

Important Note

When playing rvf files, it is important to note that some of the video insertion modes are not compatible with the full raster playout. For example, if a clip is grabbed, including the embedded audio, video index information, VITC etc, then when the clip is replayed, you probably want this embedded data to be replayed with the video. In this case, it is not possible to use XR to insert audio tones, or VITC etc onto the serial output. In case you wish to overwrite the grabbed embedded data with values that are inserted by XR, we have provided a control on the Generator page of the Video setup dialogue, which is part of the Engineering controls for the main OmniTek application.

Under 'Use blanking and ancillary data', select 'from internal generator', to have the audio, video index, wide screen signalling facilities in XR available to insert data onto the output, and remove the entire ancillary data packets from the original source material.

Alternatively select 'From Source Image (RVF)', to use the actual data from the source image, in which case all of the Gen embedded data facilities will be disabled, for all full frame images. However, they will continue to work in this mode for all video images and sequences that only contain the active video portion of the raster.

RVF File Editor (Advanced Option only)

The Advanced Option also includes a separate Windows application to let you view and edit the rvf files. This application can be run concurrently with any other OmniTek application. The initial release of this application lets you open files, and check the status of various of the ancillary data, and lets you edit the hex data anywhere within the file.

Pattern Menu

This menu lets you control various aspects of manipulating patterns.

Under **Sort** you have the choice of listing the loaded patterns in different ways.

Load loads the selected image into Gen SDRAM, and **Load All** loads all images into the SDRAM. This is useful if you have disabled automatic loading of images, which may be done in the Preferences menu choice, from the File menu.

Specify load sub-section is concerned with sequence loading (part of Motion/Capture). This item is only available if the currently selected thumbnail is a sequence. This menu selection opens a dialog that lets you specify a different frame as the first in the sequence, other than frame one which is the default. Similarly you can specify a final frame number as something less than the normal last frame. This is particularly useful with avi files which may contain more frames than the Gen frame buffer can hold. Without using this option, it is not possible to access frames at the end of the avi file.

Resize Output provides some options as to how images are resized when the image is not the same size as the currently selected resolution. The choices are the same as available from the Preferences menu choice, described on page 54.

Edit brings up an editor for line patterns, or zone plates.

Save lets you save the current image, and is intended for use with an image that has been grabbed from the live input.

Save As... lets you save the current image to a new filename, and/or in a new format. For example, an image loaded as a BMP could be saved as a JPEG, or a sequence of multiple individual frames can be saved as an AVI file. Please note that when an image is saved, it is automatically reloaded afterwards. This is in case the image format has changed, such as from BMP to JPEG, so you can immediately see that the new image format is suitable.

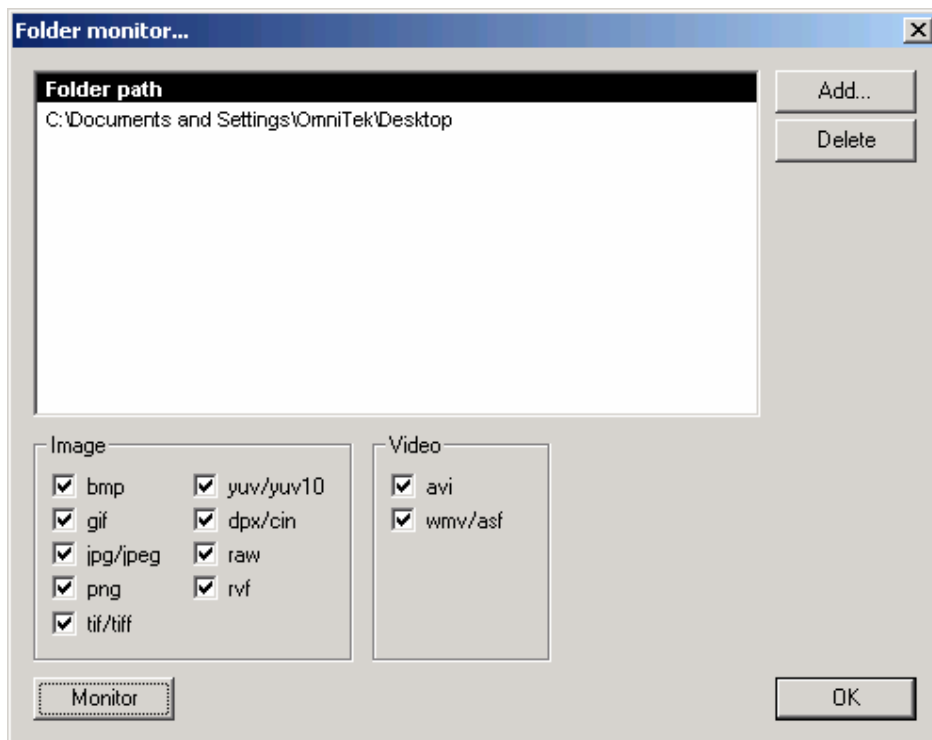

Save Frame As... is a mode used with sequences, and lets you save an individual frame from anywhere within the sequence.

Properties provides information about the current image.

Delete removes the selected image from the Gen window, and frees up the SDRAM that was occupied. It does not affect the image that is stored on disk.

File Monitor Function

XR has a file monitor function, also part of the Motion/Capture option. Once configured, XR will constantly look at the contents of specified folders, and as files appear, automatically load them.

To configure the file monitor, click 'Add' to choose the location for the monitored folder(s). Specify which file format(s) to monitor by ticking the appropriate boxes. The actual monitoring process can be enabled by either clicking the 'Monitor' button on this dialogue,

or by clicking the 'start monitoring' icon, .

This function is very useful in conjunction with remote processes that are rendering images to create clips. The images that are created can be loaded into the XR unit as they appear, and compiled into a moving sequence, or checked out using the various waveform monitoring functions that are part of XR.

Generator Playlists

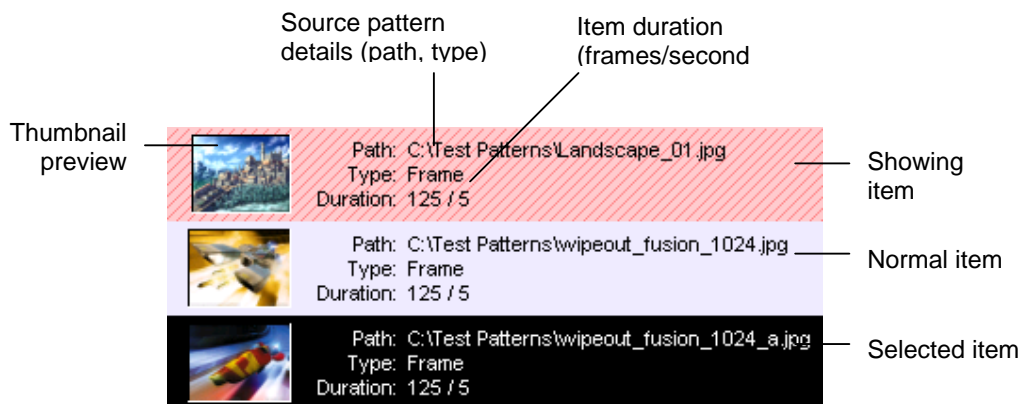

An OmniTek XR system has the ability to create and manage playlists. A playlist is, in effect a scheduled payout system that can run through a predetermined list of video images and clips, with each item in the list potentially having different audio settings, and with certain different video engineering settings, and each can be displayed for a different duration.

The playlist can be opened and closed by clicking the 'PL' toolbar button, or the 'Playlist Window' menu entry found under the 'View' menu. You can think of the playlist Window as a sub-window of the Generator window, as the playlist window can only be open when the Generator window is open.

The playlist is just like a sequence pattern, it can be played forward or backward, it can be stepped through, and you can go direct to a specific frame. The playlist 'pattern' in the Generator Window **must** be selected like you would any other pattern, at which point you can traverse the playlist using the run toolbar as you would a normal sequence. This playlist 'pattern' is the blank thumbnail in the Generator window with the word 'Playlist' written across it. It is visible at all times and is always the first 'pattern' in the configuration. Please remember that the playlist is software driven, so there will be some latency when switching patterns within the playlist, or, for example, when a playlist is stopped mid item, the software makes an estimate of the frame you have stopped at using a number of internal factors.

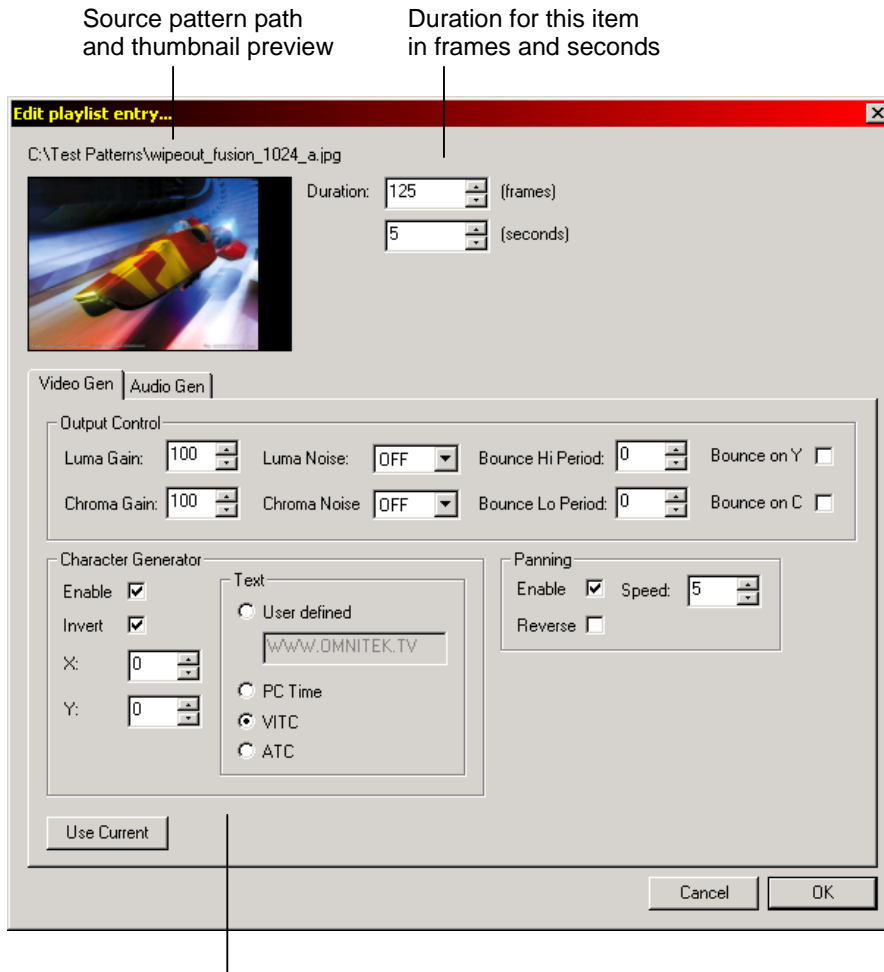

The actual playlist is created by dragging a pattern from the Gen window into the playlist window. An item from the Generator window can be dragged into the playlist as many times as required. It is not possible to drag and drop using multiple selections. Since drag and drop does not work with all PC configurations, it is also possible to right-click over an item in the Gen window, and select 'Add to Playlist...', to achieve the same effect.

The playlist Window shows items as a row entry in a list. Each entry has a thumbnail preview of the source pattern, the path and type of that pattern, and the duration in frames/seconds of that item. A 'selected' item in the playlist for editing, is highlighted in black. The currently 'showing' item is highlighted in red/pink, so it is the red/pink colour that indicates what item is currently being generated.

Add/Edit item

As previously mentioned, items can be added to the playlist by dragging a source pattern from the Generator Window. Upon doing so, an item-edit Window will appear allowing the user to specify the duration for this item and also the ability to edit various video/audio generator features such as panning, character generation, audio tones etc. These video/audio generator settings will apply to the specified item only. This allows the user to change, for example, audio channel tones for different items in the playlist.

Video/audio generator settings for this item

The item properties/edit Window is displayed when a pattern is 'drag and dropped' from the Generator Window into the Playlist Window. The Window can also be accessed for existing playlist items by double-clicking an item, using the 'Selected pattern properties' menu entry under the main 'Pattern' menu, by pressing enter, or by using the 'Selected pattern properties' toolbar button. These actions only effect the selected item. Use the 'Edit' context menu entry also to edit an item (selected or otherwise). The Window allows the user to specify in frames or seconds (for the current video-standard) how long the item should be displayed for. For frame, line, and zoneplate patterns, this same frame will be played out for this duration. But for sequences, the pattern will be played forwards or backwards in a loop for the entire duration. The 'Use Current' button can be used to set the video/audio settings for the current engineering settings.

The video/audio generator settings work in the same way as the normal video/audio generator settings found in the engineering Window.

Item order

Playlist items can be ordered (moved up and down the list) by using the up/down arrow toolbar buttons or the 'Move selected pattern down'/'Move selected pattern up' menu items in the 'Pattern' main menu. These actions will only affect the selected item. You can also move an item up or down the list by using the 'Move up' and 'Move down' context menu items; these will move any item up or down the list (selected or otherwise).

Delete item

To delete an item in the playlist use the cross toolbar button, the 'Remove selected pattern' menu item under the 'Pattern' main menu, or press the delete key. These actions will only affect the selected item. Use the context menu 'Remove' item to delete an item (selected or otherwise).

Playlist save/open/new

Playlists can be saved or opened using the 'Save playlist' or 'Open playlist' toolbar buttons or the 'Save playlist', 'Save playlist as', and 'Open Playlist' menu items under the 'File' main menu. Use the 'New playlist' toolbar button or 'New playlist' menu item found under the 'File' main menu to create a new blank playlist. Playlists are saved as .odp files. The last used playlist will be opened automatically when OmniTek LAB starts up.

Note that there is a very tight cohesion between the playlist and the Gen configuration. Since the playlist is only a set of 'instances' of patterns, the 'source' patterns have to be intact in the current configuration. If a playlist item is not found in the current configuration an error message will be displayed.

Important Notes:

When a playlist is playing, the video and audio generator settings are changed to the ones specified for the current item. If the user goes in to the normal engineering and changes the video/audio generator settings, **these will not affect the current settings** because the playlist is using its version of the settings for the current item. Therefore the normal engineering settings will not have any effect until the playlist is exited.

The screenshot displays two windows from the Generator software. The left window, titled 'Generator Playlist', shows a list of items with columns for path, type, and duration. The first item is highlighted in red/pink, and a context menu is open over it, showing options like 'Edit', 'Remove', 'Move Up', and 'Move Down'. The bottom of this window shows a status bar with '# Patterns: 7' and 'Total duration: 1000 frames/40 seconds'. The right window, titled 'Generator', shows a grid of pattern thumbnails. The top-left thumbnail is highlighted in black, indicating it is the selected item. Annotations with arrows point to various UI elements in both windows, including toolbar buttons for 'New playlist', 'Open playlist', and 'Save playlist', and menu items for 'Edit selected item', 'Delete selected item', and 'Move selected item up/down'. The 'Playlist pattern' label points to the grid of thumbnails. The 'Playlist status text' label points to the status bar in the left window, and the 'Item details' label points to the information shown for the selected item in the right window.

Annotations:

- Edit selected item
- Delete selected item
- Move selected item up/down
- Playlist pattern
- New playlist
- Open playlist
- Save playlist
- Showing item (in red/pink)
- Playlist item
- Selected item (in black)
- Playlist status text (total number of items, total duration)
- Item details (path, type, and duration)

Generator

There are a number of occasions where a playing playlist will be stopped:

- An item is added, edited or deleted
- The pattern in the Generator Window is changed
- The order of the items in the playlist Window are changed
- A new Generator configuration is created, or a new configuration is loaded
- A source pattern used in the playlist is deleted from the Generator configuration
- A source pattern used in the playlist is loaded into SDRAM
- A new playlist is created or a playlist is loaded
- The video standard is changed.

8 Other Features

Status Bar

At the bottom of the main application window, there is a status bar.

The currently selected video format is display. Note that this may not reflect the standard of a video source connected to the unit.

The status of the analog reference, and the serial input are then displayed. The items are colour coded to indicate status. If the colour is orange/brown, then the item listed is incorrect in some fashion, but is not being used. If the colour is red, then it is incorrect, and is being used. If green, then it is OK.

The current colour space mode for waveform display is also indicated. This will be YUV or RGB parade, or YUV or RGB component. This choice is independent of the format of the serial video data.

The waveform mode is indicated. This can be All line, single line, or frame view.

Finally the current selection from the four available work surfaces is indicated.

At the very right hand is a little field interrupt indicator. This spins during normal operation, indicating field interrupts are being processed. It will stop during certain operations, such as loading files from disk.

Miscellaneous Features

OmniTek XR contains a variety of minor features all designed to make the product more useful and easy to use. Some of these are described here.

Window sizes

The size of all of the windows is related to the video standard. If you position and size the windows in a given standard, then they may well be too small or too large in the new standard. If you right click on many of the windows, then a menu appears with a resize to fit option. Select this, and the window will become the minimum size to suit the data being displayed.

Size and Position Snap

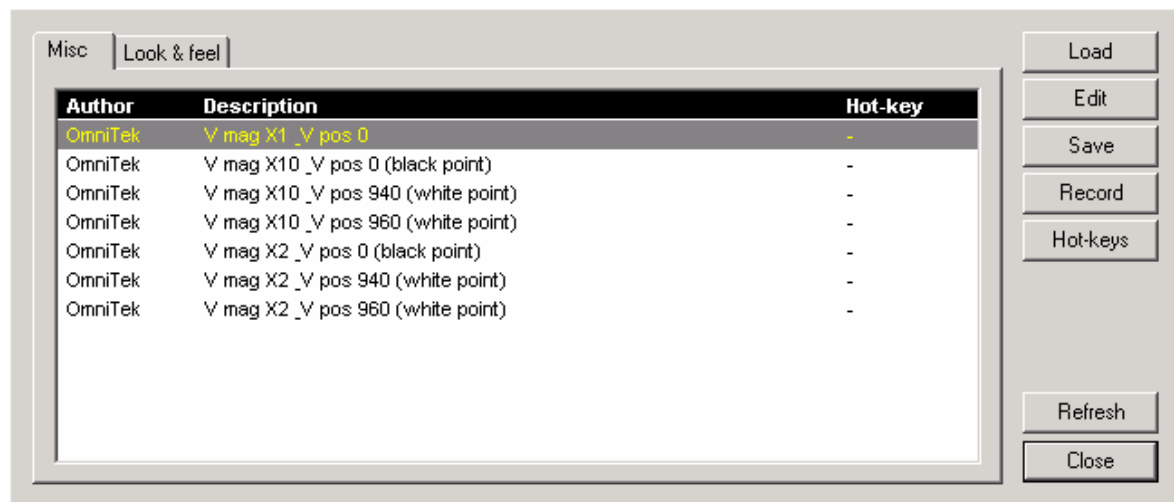

By default, windows will be set to 'jump' if they are sized or moved. This works as if the windows are magnetic, so a window placed near another one will jump to line up with the edge of the other window. This is not a jump to grid function. This mode of operation can be confusing sometimes, and if you wish to position a window adjacent to two others, it may be necessary to move one away whilst the move is taking place, and to put it back afterwards. By right clicking on a window, you get an option to disable this magnetic jumping function, so that windows can be moved to any position, regardless of what is nearby. If you subsequently use the menu to enable the magnetic jumping feature, then this will only take effect next time you move/size the window – it won't affect the current size and position.

'Shift' Keyboard Shortcuts

At any time you may press and hold the 'Shift' key. A small menu appears providing immediate access to some common functions. The menu disappears when either a function is activated, or the Shift key is released. Of particular use, Shift-E immediately opens the Engineering dialogue.

The other particularly useful 'Shift' shortcut, is Shift-P, which opens the Presets configuration dialogue.

Presets

Presets are individual macros that can be assigned to hotkeys. Presets can be freely assigned to Shift-F1 through to Shift-F12. Presets work in both the normal Windows environment, and in the full screen modes.

To create a new preset, press the 'Record' button. All actions that are performed are captured, right up until the Stop button on the Presets window is pressed. (The Record button is replaced with a Stop button during Record mode).

Once Stop is pressed, a dialogue appears to let you assign a name to the preset, as well as specify the authors name, and a description of the preset. The description appears in the Preset window shown above.

Once the preset is created, it should be assigned to one of the twelve Shift-function keys, by pressing the 'Hot-Keys' button.

Once a preset has been created, the essential control elements are distilled into a text file. Selecting a given preset and pressing 'Edit' opens a text editor. Although care needs to be adopted, it is possible to edit the text file, and save it back again.

Presets are particularly useful for changing settings such as switching from single line to multi-line mode, and can be used independently of the assignable full screen modes, which are also assigned to hotkeys.

A1 File Types

Current OmniTek systems use some unique file types. This section explains what type of data is held in each file type.

.ods (OmniDesktop Settings)

Stores everything: all user configurable engineering settings, the four layouts (pages), and all other misc settings and preferences. Note that OmniTek saves a .ods file when it is closed down, and opens that same file when it next starts up, ensuring the system is in the exact same state in was last in (called 'startup.ods' and is located in 'program files\omnitek\omnitek'). OmniTek allows the user to optionally load a .ods file at startup, make sure the 'At start-up prompt to load system configuration' option is checked in the File->Preferences menu.

.ode (OmniDesktop Engineering)

Stores all user configurable engineering settings (those settings configurable via the engineering Window).

.odl (OmniDesktop Layout)

Stores layout information for current page: child Window position, size, snap. Z-order of child Windows. Toolbar visibility, position. Layout name. Line-data Window: visible sections for RGB/YPbPr colour modes. Video-status Window: visible items.

.ogs (OmniGen Setup)

Stores the generator configuration: default resize type, pattern path, resize type, and load status. Selected pattern. List/thumbnail mode.

.ini (Initialization)

Generic data is stored in ini files. OmniTek uses three .ini files, one for the full-screen-layout definitions (full_screen_layouts.ini), one for range-error profiles (analyzer_range_error_profiles.ini), and one for cage safe-title profiles (cage_safe_title_profiles.ini). All of these ini files are stored at the same level as the OmniTek executable (usually at c:\program files\omnitek\omnitek).

.xml (Extensible Markup Language)

The main event log and the picture quality time-based log are stored/loaded as XML files.

Generator patterns

Extension	Input	Output	Description
bmp	x	x	Bitmap
jpg/jpeg	x	x	JPEG
tif	x	x	TIF (Tagged Image File Format)
gif	x	x	GIF (Graphics Interchange Format)
png	x	x	PNG (Portable Network Graphics)
yuv	x	x	YUV 8 bit-per-pixel (8 (U), 8 (Y), 8 (V), 8 (Y))
yuv10	x	x	YUV 10 bit-per-pixel (10 (V), 10 (U), 10 (Y), 2 (padding))
dpx	x		DPX (Digital Moving-Picture Exchange)
cin	x		Cineon
rvf	x	x	Raster Video Format, SINGLE-LINK ONLY, stores active video AND blanking
raw	x	x	Raw active video, DUAL-LINK ONLY, (V/R (10), U/B (10), Y/G (10), 2 (padding))
lpd	x	x	Line pattern
zpd	x	x	Zoneplate
avi	x	x	Microsoft Audio/Video Interleaved
wmv	x		Windows Media Video
asf	x		Microsoft Windows Media Advanced Systems Format

A2 Logging

Configuring Logging, and SNMP alerts

OmniView now contains a comprehensive logging package. The system has the ability to make entries into an XML log file whenever specific conditions occur. It can also transmit an SNMP alert based on certain conditions occurring. These two functions work independently. Both log entries, and SNMP alerts, can include VITC or ATC if present, and the current time.

Logging Configuration and use

Clicking on the  icon opens the Event log window, as shown below.

The window shows 'live' logging as it happens. The data is not written to a log file unless the green 'Start' button is pressed. At this time, all log entries are written to a temporary file. When 'Stop' is pressed, logging stops, and a dialog box opens to let the user choose a name for the log file.

Each line in the Event Log window starts with one of three icons. To reduce the number of entries, events are shown as starting on a given frame, and then being continuous for a period, and then stopping on a given frame, rather than each occurrence getting an individual entry. So the three icons used have the following meanings.

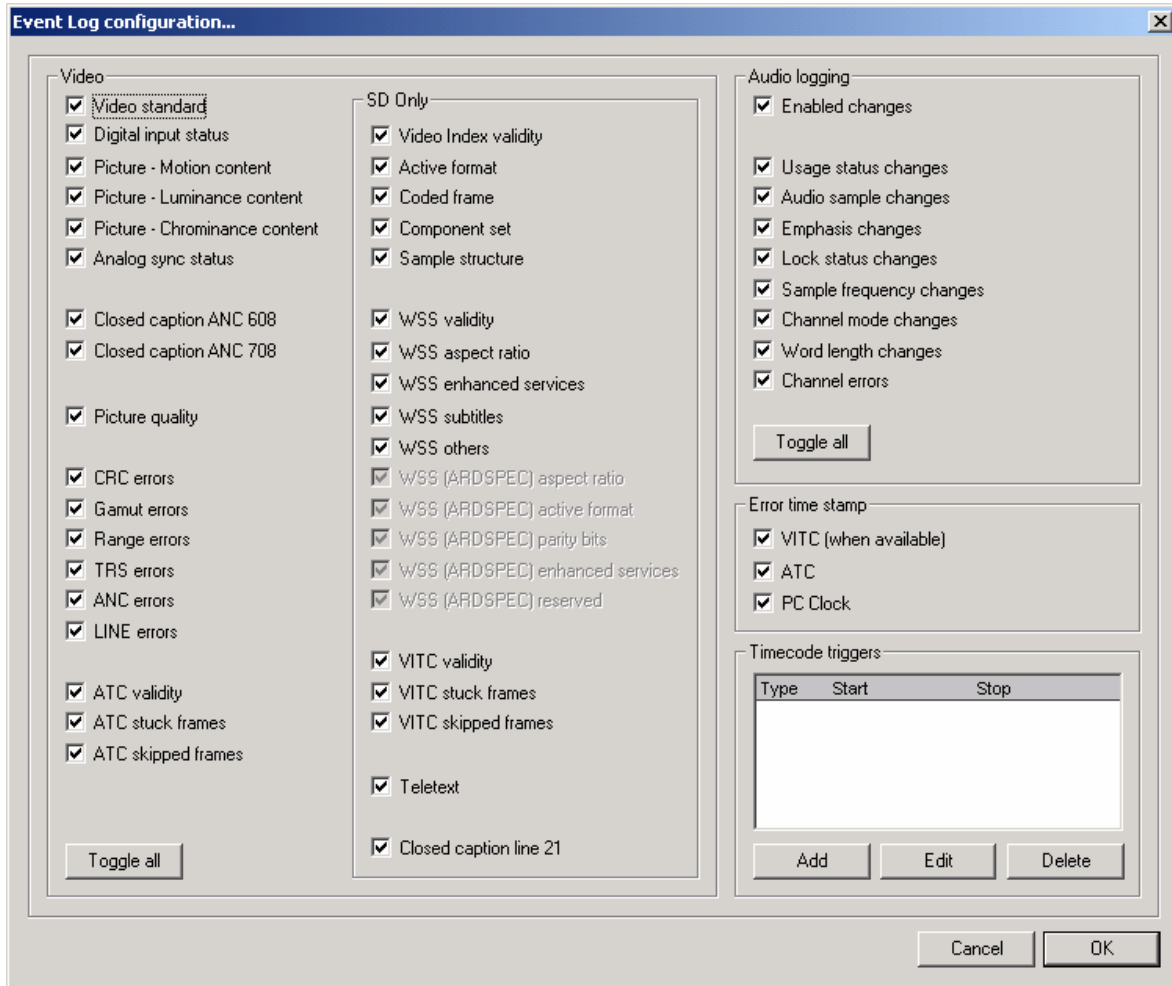

The named event started and continued for every frame

The named event had been occurring on every frame, but stopped at this point.

The named event only occurred on this frame.

Clicking on the  button opens the configuration dialog for logging.

Every parameter that can be logged is shown on this dialogue. There is a check box adjacent to each parameter. If the check box contains a solid 'tick', as shown above, then occurrences of the parameter is written into the XML log file, with the word 'ERROR' next to it.

If the check box contains a grayed out tick, then occurrences of the parameter is written into the XML log file, with the word 'WARNING' next to it.

If the check box is not ticked at all, then the associated parameter is not included in the XML log file.

Each time you click in each check box, the state cycles from 'log as ERROR', to 'log as WARNING', to 'not logged', and then back to ERROR, and so on.

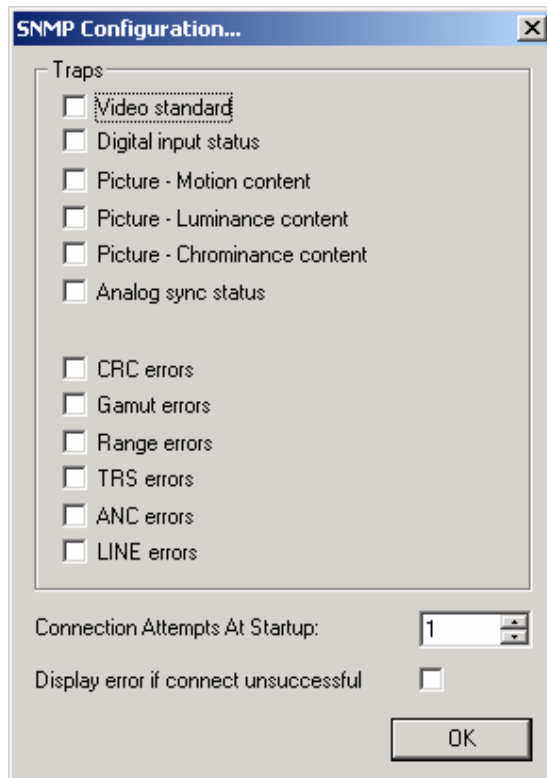

Note that certain parameters only exist in SD. These are Wide screen signaling, Video Index, and VITC, so these selections are not available in HD. The system supports two different specifications for Wide Screen Signalling, and only one specification is supported at a time. To choose which specification, go to the Wide Screen Signalling section of the main Engineering dialog.

It is possible to select VITC or ATC timecodes to be included in the log file. VITC only exists for SD signal. The ATC packet can be loaded with LTC, or VITC 1 or VITC 2. The particular timecode type is set on the Timecode section of the main Engineering dialog.

As well as always logging chosen parameters, you can use the "Timecode Triggers" section to only log between certain timecode values. Use the 'Add' button to set these up.

SNMP Configuration and use

The SNMP configuration dialog is accessed from the main Configuration menu.

You can use this dialogue to specify which of the listed conditions should be used to send SNMP traps. Each item will send a trap every time the specified error condition occurs, or clears. For example, if Picture Quality is selected, the application will transmit an SNMP trap when the picture quality drops below the threshold, and again when the picture quality rises above the threshold. This set of parameters is not filtered in anyway, so there are no timeouts affecting whether the parameters are sent. In this way, a remote monitoring application will receive all the raw data, and the user can control and change their own filtering as required.

When the OmniTek application starts up, it will always check to see if an SNMP service is running on the host PC. The number of attempts to connect can be set here, as well as an option warning of connection fails.

SNMP Configuration Problems.

The SNMP service is an optional Windows component, and is not installed if a standard Windows installation was done. OmniTek has produced a short document describing how to add the SNMP service onto a PC. This document is called 'SNMP installation guide.pdf', and is available from our FTP site. It is also available in the user manuals section of our website. Visit www.omnitek.tv, then select 'support', and then click 'SNMP Installation Guide, for use with Quality Auditor'. This document is also available on request from your dealer.

When the SNMP service is running, note that by default, Windows will send SNMP traps only to the host machine - ie only to itself. To send the traps to other machines, you need to configure the trap addresses. This is done by opening the Control Panel, then selecting 'Administrative Tools', and then selecting 'Component Services'.

Select the 'Services (Local)' item in the left hand pane, and then scroll down to the 'SNMP Service' item in the right hand pane. Double click the 'SNMP Service' item, and then go to the 'Traps' tab.

You can now add, delete or edit the IP addresses where traps are sent. You'll probably see a single entry in the 'Trap Destinations' list box, called 'localhost'. 'localhost' is the IP address of the 'local' machine, which means that traps are sent and received by the local machine, and do not go to other machines. You can enter multiple IP addresses, so that the traps are sent to multiple machines.

MIBs for OmniTek products may be downloaded from the Support section of the OmniTek website, www.omnitek.tv

A3 Measuring Audio/Video Delays

An OmniTek system can be used to measure either absolute audio and video delays through external equipment, or can measure the relative delay between the audio and video paths. The OmniTek modules and options required are different between the two modes. The Advanced Option is required. This appendix describes what OmniTek products are required for each mode, and how to configure the OmniTek system in each mode.

Both measurement modes rely on the use of a special full-motion video test sequence which contains precise embedded audio tones. This sequence is available for all standard-definition and high-definition video formats, and may be played out either from an Gen signal generator (equipped with the Motion option) or simply from a videotape machine or video file server.

The following sections describe the OmniTek delay test sequence, and show how it may be used to perform audio and video delay analysis on external equipment.

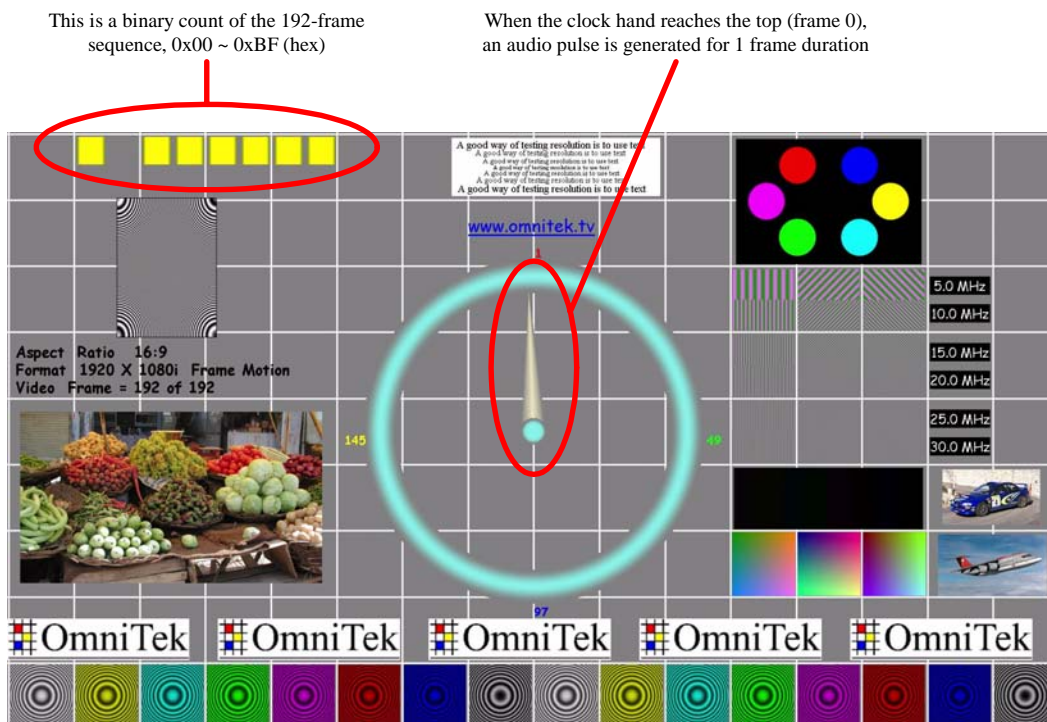

A/V Delay Test Sequence

OmniTek have generated a special full-motion video sequence, 192 frames in duration. This is available in all video formats, both standard- and high-definition. The test sequence contains many elements which are useful for testing and analysing the performance of a video system, however for the purposes of the audio/video delay measurement there are two characteristics which are of special importance:

On the first frame of the sequence only, an embedded audio tone of 8kHz is generated on channel 1 at a level of $-18\text{dB}(\text{FS})$.

In the top left-hand corner of each frame, a binary frame count is displayed as a sequence of yellow squares.

In the View analysis software, the binary frame count can be extracted from the input video image, and the embedded audio tone is also detected. The relative timing of the audio tone to the first video frame in the sequence indicates the delay between audio and video components.

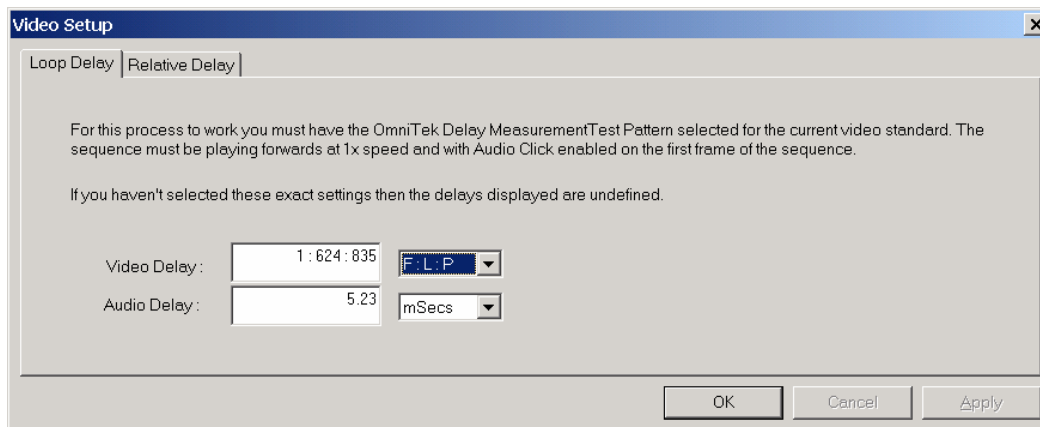

Loop A/V Delay Testing

In this mode, the absolute video and audio delays are measured between the input and output of the OmniTek system. The A/V Delay Test Sequence is output using the Gen signal generator, and the signal is taken directly to the equipment under test. The output from the equipment is fed straight back to the View input.

The View analysis software compares the timing of the output video and embedded audio with the input video/audio timing. The total propagation delay through the external equipment is calculated and displayed.

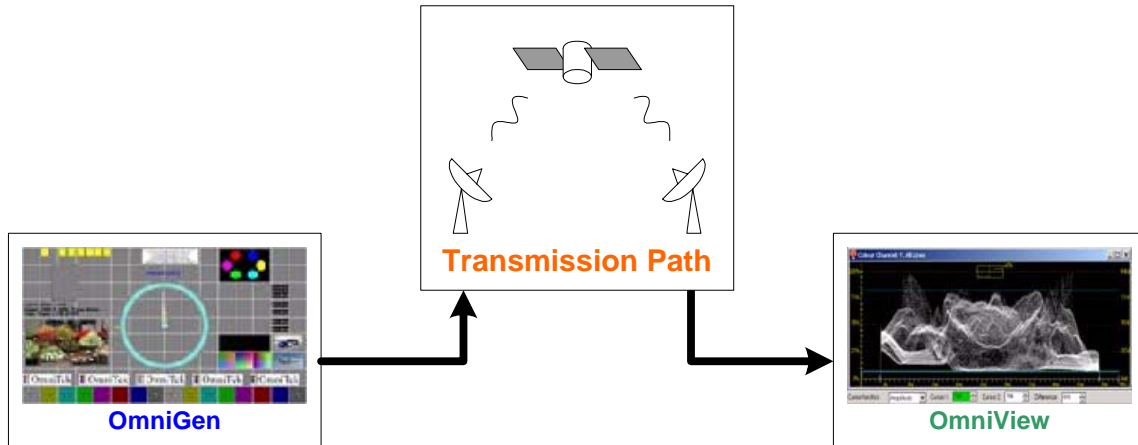

The time delay range that the system is capable of measuring is:

	50Hz Systems	60Hz Systems
Audio delay:	0 ~ 7680 ms	0 ~ 6400 ms
Video delay:	0 ~ 7680 ms	0 ~ 6400 ms.

The time delay measurement for the audio may be displayed as samples (at 48kHz) or milliseconds. The video delay may be expressed as "Frames : Lines : Pixels" or milliseconds. In all cases, measurement accuracy is better than 1 ms.

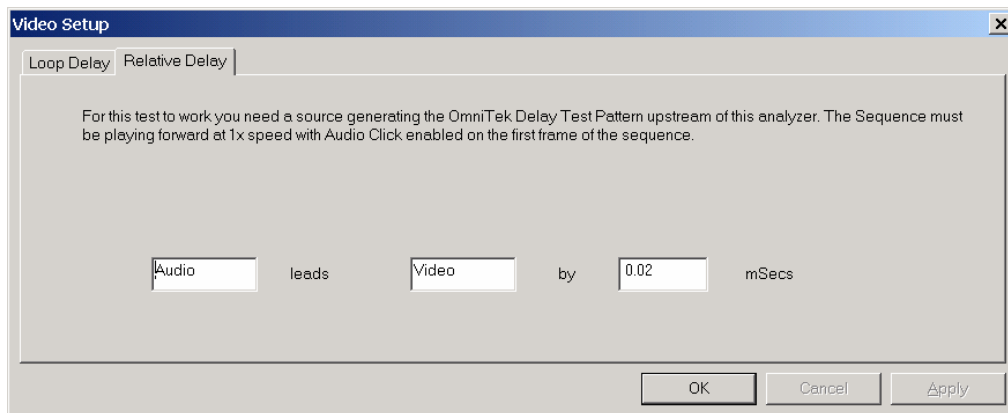

Relative A/V Delay Testing

In this mode, the relative delay between audio and video is measured. The OmniTek A/V Delay Test Sequence generator may be installed remotely to the video analyzer, which means that it is possible to measure A/V delays in satellite, cable, or terrestrial broadcast links.

Note that the delay test sequence may be played out from an Gen system, a videotape machine, or a video file server.

In this mode, the View software analyses the input video signal, looking for the first frame in the sequence (identified by the binary code). When this is detected, an internal timer counts the time delay before the audio input pulse is detected. The system automatically detects whether the audio pulse is early or late with respect to the video, and displays the results accordingly.

The delay range that the system is capable of measuring is:

	50Hz Systems	60Hz Systems
Audio early with respect to video:	0 ~ 5760 ms	0 ~ 4800 ms
Video early with respect to audio:	0 ~ 1920 ms	0 ~ 1600 ms.

The relative time delay measurement is always expressed in milliseconds, and the accuracy is better than 1 ms.

Setting up the OmniTek System

This section explains how to set up the OmniTek system to perform the delay testing operations.

Gen Setup

If Gen is to be used for generating the special A/V Delay Test Sequence, this is the sequence of operations required:

1. Set the Gen system to the correct video format in the “Engineering > Video Setup > General” menu.
2. Make sure no other images are loaded into the Gen desktop.
3. Load the 192 frames of the special A/V Delay Test Sequence that is applicable to the current video format. Choose the “no fit” option if necessary. Then play the sequence in an endless loop, by using the icons on the transport toolbar.

4. In the menu “Engineering > Audio Setup”, make sure that the audio tone on channel 1 is set for 8kHz, -18dB, and present only on frame 1 of the sequence. This setting is essential for correct operation.

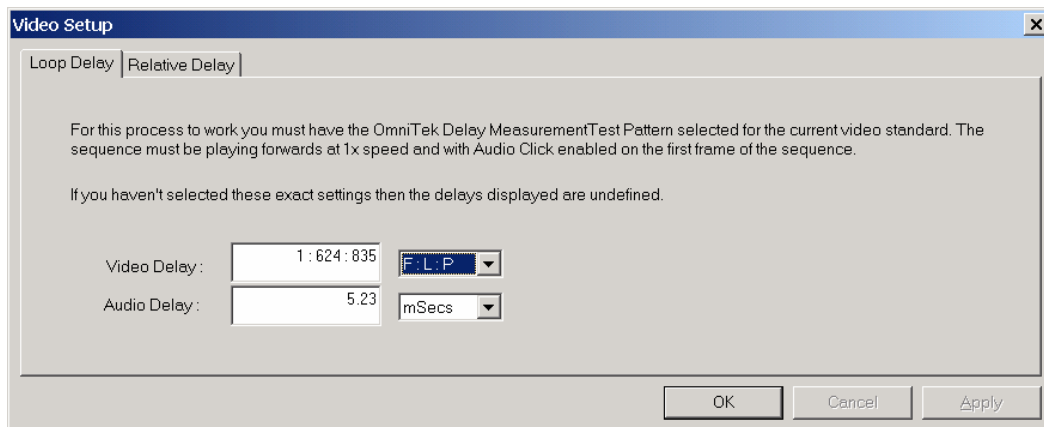

View Setup

Set the source routing such that the serial output from the OmniTek system is coming from the Gen test sequence, and the analyzer input is connected to the serial input.

Enable the A/V Delay Measurement dialogue by selecting 'Delay measurement...' from the Analyzer menu.

Select "Loop Delay" or "Relative Delay" on the dialogue box, to choose the measurement type to be performed.

The audio and video delay values will be displayed on the dialogue box. Please note that the delay calculations are performed once for each loop around the 192-frame video sequence, therefore there is a latency of several seconds before new delay readings are displayed.
